ABSTRACT

Seismic design and assessment methods for structures vary in approach. This pilot investigation thoroughly examines the correlation between ASCE/SEI 7-10, *Minimum Design Loads on Buildings and Other Structures*, design methods and ASCE/SEI 41-06, *Seismic Rehabilitation of Existing Buildings*, assessment methods. The project focuses on reinforced concrete buildings composed of 'Special Reinforced Concrete Moment Resisting Frames' and 'Special Reinforced Concrete Shear Walls'. A primary goal of this pilot project is to identify typical inconsistencies or modeling issues for a single building, to provide a guide for the larger and more comprehensive parent investigation. A full seismic design of an archetype structure, using ASCE/SEI 7-10 is completed using both the Equivalent Lateral Force method (for drift) and the Modal Response Spectrum Analysis method (for strength).

Assessment methods in ASCE/SEI 41-06 include linear and nonlinear procedures. Linear procedures model components as perfectly elastic, while approximating nonlinear stress-strain behavior through the use of global stiffness reduction factors. Typically, these methods provide conservative but simple approximations of component behavior. Nonlinear methods incorporate the use of stress-strain relationships beyond the elastic limit, capturing more accurately the nonlinear behavior of a material. Although not exact, this approximation typically provides a more accurate representation of overall system behavior.

Using these linear and nonlinear methods prescribed in ASCE/SEI 41-06, the archetype structure was found to exhibit a large number of component failures, both in flexure and shear. Linear methods, static and dynamic, yielded the highest percentage of failures, indicating notable inconsistencies between design and assessment methods. Additionally, analysis using nonlinear dynamic analysis, based on ASCE/SEI 41-06 parameters, results in a 50% collapse rate, with respect to time history records, at the collapse prevention seismic hazard level. In a practical design situation, these results would require the structure to be either redesigned or retrofitted, and reevaluated. The findings of this pilot investigation indicate the need for further, larger scale evaluation of design and assessment methods for various structure layouts and types.

EXECUTIVE SUMMARY

Modern seismic design is strictly governed by building code requirements, such as those found in ASCE/SEI 7-10, *Minimum Design Loads for Buildings and Other Structures*. Similarly, modern seismic assessment of existing buildings (and seismic rehabilitation) is governed by requirements found in ASCE/SEI 41-06, *Seismic Rehabilitation of Existing Buildings*. However, few studies have examined the agreement between code requirements for design and assessment. The following report is a pilot investigation into the correlation between design and assessment methods for reinforced concrete lateral systems. The report focuses on ‘Special Reinforced Concrete Moment Resisting Frames’ and ‘Special Reinforced Concrete Shear Walls’. The parent project aims to relate design and assessment for a broad spectrum of building layouts and heights, for both reinforced concrete and structural steel lateral resisting systems.

The first phase of the project involves familiarization with all pertinent design and assessment codes and methods, as well as a review of related research. During this process, design and assessment spreadsheets are developed to maintain efficiency throughout the project.

The second phase of the project includes a full seismic design of an archetype structure using ASCE/SEI 7-10 provisions. The structure is composed of ‘Special Reinforced Concrete Moment Resisting Frames’ in one orthogonal direction, with ‘Special Reinforced Concrete Shear Walls’ in the other. The building is analyzed for drift using the Equivalent Lateral Force method, and analyzed for strength using the Modal Response Spectrum Analysis method, both as prescribed in ASCE/SEI 7-10. As the lateral systems in use are primarily reserved for regions with higher seismicity, Seismic Category D is assigned to the structure. Additionally, the pilot project focuses on the upper-bound, or D_{MAX} , seismic hazard; the parent project will encompass both D_{MAX} and D_{MIN} seismic hazards. Wind analysis is also performed to ensure that seismic actions govern the behavior of the structure.

Lastly, the archetype structure is assessed under ASCE/SEI 41-06 provisions. Within ASCE/SEI 41-06, various earthquake hazards, based on probability of exceedance, are used to assess the structure for varying levels of damage. These hazards, called performance objectives, include Immediate Occupancy, Life Safety, and Collapse Prevention. Immediate Occupancy relates to minor and repairable structural damage, which does not prevent immediate re-occupancy of the building. Life Safety involves repairable structural damage to the building, with the possibility for typically non-life-threatening injuries. Lastly, Collapse Prevention refers to major structural damage, and typically imminent collapse. Often times, structural damage at the collapse prevention level cannot be practically repaired.

ASCE/SEI 41-06 provides four different methods for assessment of existing buildings. These methods include the linear static procedure, the linear dynamic procedure, the nonlinear static procedure, and the nonlinear dynamic procedure. Linear methods are based on elastic theory of materials. In general, stiffness reduction factors are used to approximate nonlinearities in a system. These procedures are typically more conservative, but also provide a simple and functional model of the system. Nonlinear

methods are based on the full stress-strain relationships of specific materials. Nonlinear modeling includes stress-strain relationships beyond the elastic limit, and therefore can capture strain-hardening and strain-softening effects. Static methods employ the use of pseudo-lateral forces, similar to the Equivalent Lateral Force method in ASCE/SEI 7-10, as well as pushover analysis for the nonlinear static procedure. These methods are typically a conservative approximation of the behavior of the structure during a seismic event. Conversely, dynamic methods use response spectrum analysis and time history analysis, both of which more accurately represent the seismic demands on a structure through inertial forces. As this investigation aims to correlate design and assessment as a whole, all four methods are evaluated.

The results of this investigation indicate inconsistencies between seismic design and assessment. Specifically, the use of linear procedures results in flexural and shear failures in both the moment frames and the shear walls. These failures are likely due to the variance in modeling and analysis between design and assessment. For example, stiffness reduction factors are much lower using ASCE/SEI 41-06. This leads to larger deformations, and as a result, larger demands. Additionally, the actions on the structure are much higher using ASCE/SEI 41-06. ASCE/SEI 41-06 adjusts component capacities to account for ductility, where ASCE/SEI 7-10 reduces actions based on ductility of the system. Although this poses difficulties for comparison, the results of this investigation do indicate differences in the end result.

Nonlinear methods yielded fewer failures, although under these procedures the archetype structure does not satisfy all ASCE/SEI 41-06 requirements. Additionally, nonlinear dynamic analysis yielded a 50% collapse rate (in terms of time history records) at the collapse prevention performance objective. As a result, in a practical situation, the archetype structure would require redesign.

It is important to pursue further evaluation of design and assessment methods. This pilot investigation was successful in locating notable discrepancies between the two methods, which should be examined on a large scale, as is intended in the parent project. Specifically, the linear procedures appear to be overly conservative, yielding high rates of component failures. Nonlinear procedures, however, are also worthy of further review for comparison, as a number of catastrophic failures occurred as a result of these methods.

ACKNOWLEDGEMENTS

This project was financially supported through an ongoing parent project, *Assessment of First Generation Performance-Based Seismic Design Methods for New Concrete Buildings*, at the National Institute of Standards and Technology (NIST), Building and Fire Research Laboratory. Throughout the investigation, immediate guidance and support was provided by Dr. Jeff Dragovich and Dr. Jack Hayes, both members of the National Earthquake Hazards Reduction Program (NEHRP) at NIST. Additionally, academic advising and oversight was provided by Dr. Larry Fahnstock of the Civil and Environmental Engineering Department at the University of Illinois at Urbana-Champaign. I would like to thank each of them for their advice and suggestions throughout this duration of this project. This project was only made possible through their invaluable contributions.

1. INTRODUCTION

Seismic analysis of buildings plays an integral role in modern structural engineering practice. Such analyses can be applied to design, rehabilitation, and assessment, amongst others uses. However, the method with which seismic analysis is used in these applications varies. Specifically, methods with which new buildings are designed to resist seismic motions differ from those used to assess existing buildings. The following report outlines an investigation in which an archetype structure, designed using contemporary methods governed by ASCE/SEI 7-10, *Minimum Design Loads for Buildings and Other Structures (ASCE, 2010)*, is assessed for compliance with assessment criteria prescribed by ASCE/SEI 41-06, *Seismic Rehabilitation of Existing Buildings, (ASCE, 2006)*.

This project is a pilot investigation for a larger ongoing project. The parent investigation aims to evaluate archetypal structures of various heights and layouts, including both reinforced concrete and structural steel buildings. This pilot investigation helps to provide a guide through the entire process for the large scale project, surfacing areas of concern and possibilities for increased efficiency.

Specifically, this investigation examines reinforced concrete structures, composed of commonly used lateral resisting systems; reinforced concrete moment frames and reinforced concrete shear walls will be evaluated. In order to practically evaluate the archetype structure, an upper-bound seismic hazard is used for design and assessment. In regions of such high seismicity, codes require that reinforced concrete structures adhere to strict detailing requirements. These requirements are implemented in “Special Reinforced Concrete Moment Frames” and “Special Reinforced Concrete Shear Wall”, as defined in ASCE/SEI 7-10. This report focuses solely on these lateral resisting systems in its evaluation.

Prior to the design phase, a detailed review and familiarization with current design practices was completed. For this purpose, the design example in Chapter 7 of FEMA P752, *NEHRP Recommended Provisions: Design Examples, (FEMA, In-Print)*, was thoroughly completed. This process ensures that every detail of design, prescribed in either ASCE/SEI 7-10 or ACI 318-08, *Building Code Requirements for Structural Concrete and Commentary, (ACI, 2008)*, is understood and implemented correctly. During this phase of the project, a design spreadsheet is developed for use in design of the archetype structure, using Microsoft Excel. Similarly, prior to the assessment phase of the project, a comprehensive review and familiarization of assessment methods in ASCE/SEI 41-06 was completed. An assessment spreadsheet is also developed using Microsoft Excel to maintain efficiency during the actual assessment phase.

2. ARCHETYPE STRUCTURE ANALYSIS AND DESIGN

2.1. Seismic Hazard Definition and Design Criteria

Development of Seismic Hazard for the archetype structure considers documentation within FEMA P695, *NEHRP Quantification of Building Seismic Performance Factors, (FEMA, 2009)*, which uses probabilistic regions of Maximum Considered Earthquake (MCE) ground motions, as defined in ASCE/SEI

7-10 Section 21.2. FEMA P695 also provides lower and upper bounds on the short-period and 1-second spectral response accelerations, S_s and S_1 . The investigation is limited to the upper bound ground motions (denoted D_{max}). The archetype structure is not located in a specific region, and therefore is assigned to Site Class D as required in ASCE/SEI 7-10 Section 11.4.2. Design parameters are calculated using ASCE/SEI 7-10 Chapter 11 methods, calculations for which are located in Appendix A. Table 1 shows the Seismic Hazard for the archetype structure.

Table 1. D_{MAX} Seismic Hazard Parameters

Design Category	S_s (g)	S_1 (g)	S_{DS} (g)	S_{D1} (g)
D_{MAX}	1.50	.60	1.00	.60

As permitted in ASCE/SEI 7-10 Section 12.6, both Equivalent Lateral Force (ELF) and Modal Response Spectrum Analysis (MRSA) are used in the design of the archetype structure. Development of the Response Spectrum conforms to ASCE/SEI 7-10 Section 11.4.5. Figure 1 shows the calculated response spectrum corresponding to D_{MAX} design parameters.

Figure 1. ASCE/SEI 7-10 Design Earthquake Response Spectrum for Seismic Design Category D

The archetype structure, although simplified, is intended to emulate a multi-story mixed use (retail and office) building, with basement parking levels. Corresponding live loads conform to ASCE/SEI 7-10 Table 4-1. A typical cladding load of 15 PSF (vertical) is applied to at the perimeter of the structure. Table 2 shows the uses and super-imposed loads for each level in the archetype structure. Wind loads are also considered in the design, using a 3-second gust speed of 115 mph at an Exposure Category C. These parameters are representative of typical upper-bound, non-hurricane zone wind speeds. ASCE/SEI 7-10 Figure 26.5-1A provides guidance for obtaining such 3-second gust wind speeds.

Table 2. Building Uses and Live Loads

Level	Use	Live Load (PSF)	Partition/Roofing Load (PSF)	M/E/P/Ceiling Load (PSF)
Roof	-	20	10	10
Level 08	Office	50	15	10
Level 07	Office	50	15	10
Level 06	Office	50	15	10

Level 01	Retail	100	15	10
Level A	Parking	40	15	10
Level B	Parking	40	15	10

2.2. Structural Layout and Configuration

The layout of the archetype structure is the result of maintaining simplicity while ensuring modern design practices. In order to provide simplicity, a rectangular floor plan with orthogonal lateral resisting systems is used. In addition, the lateral resisting systems do not share common components, eliminating the need for concurrent lateral loading requirements. During the initial design phase, multiple floor plan options are reviewed by licensed professional engineers to ensure a practical design. Additionally, specific layout details such as bay widths, story heights, and preliminary sizes are chosen to closely resemble previously peer reviewed structures. Both FEMA P752 and Haselton (2006), *Assessing Seismic Collapse Safety of Modern Reinforced Concrete Moment-Frame Buildings*, are used for this purpose. Figure 2 shows the final floor plan layout for the archetype structure.

The finalized layout is composed of two perimeter lines of Special Reinforced Concrete Moment Resisting Frames in the East-West (E-W) direction, and 4 full height Special Reinforced Concrete Shear Walls in the North-South (N-S) direction. Interior and exterior columns not acting as part of the lateral systems are designed to resist gravity loads only. Interior beams are designed to resist gravity loads only, and are configured to provide a one-way slab system with a 4-1/2 inch thick slab spanning 10 feet. Throughout the structure, beams acting as part of the moment-resisting frame are 24 inches wide by 32 inches deep, while the interior beams are 16 inches wide by 20 inches deep. Columns throughout the structure are 28 inches square. The shear walls are 16 inches thick, with columns acting as boundary elements on each side of each wall. All structural reinforced concrete members use normal weight concrete with f'_c of 5000 PSI and ASTM A615 reinforcing steel.

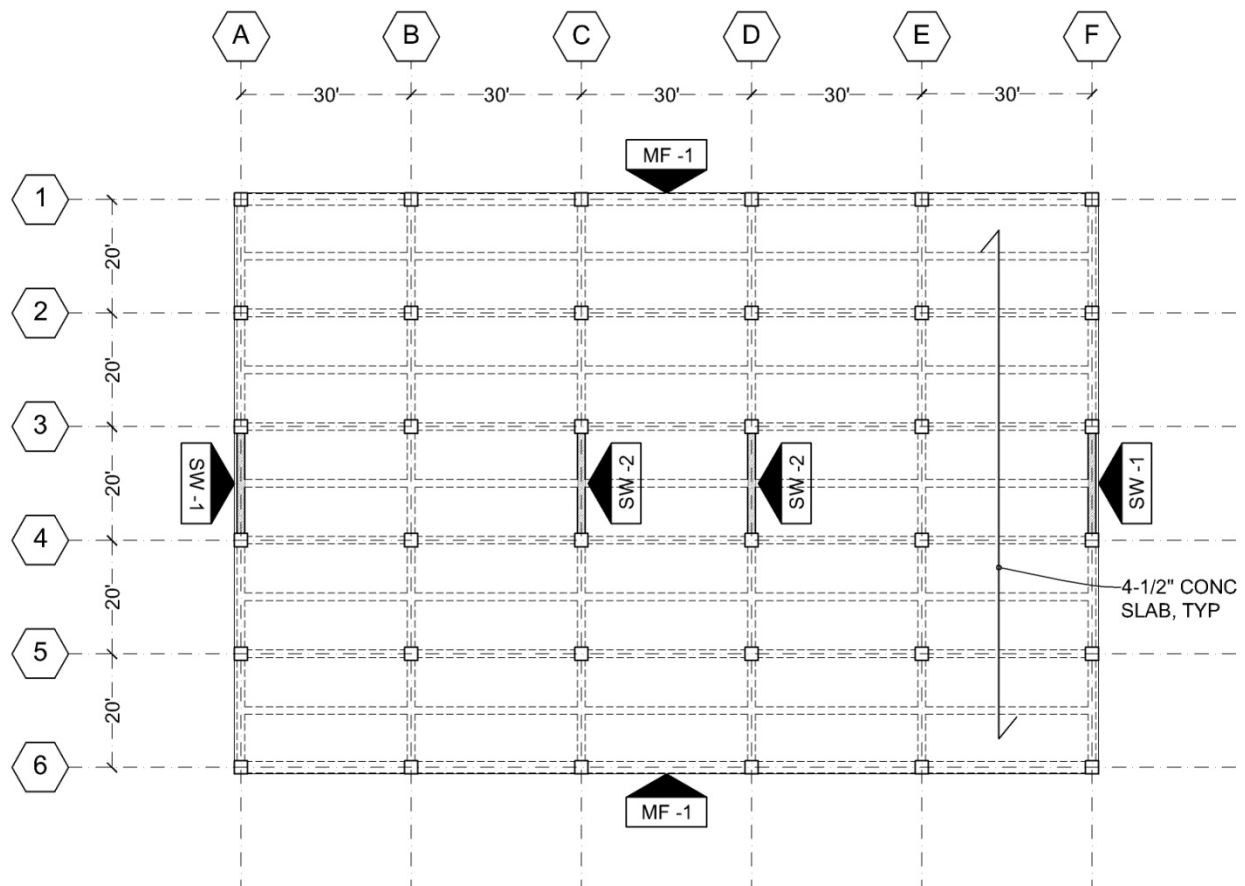

Figure 2. Archetype Structure Floor Framing Plan

2.3. Analysis Methodology

In modern building design, there are three analysis methods used to determine the seismic behavior of a structure. As noted in ASCE/SEI 7-10, these methods include the Equivalent Lateral Force (ELF) method, the Modal Response Spectrum Analysis (MRSA) method, and the Time History Analysis (THA) method. Additionally, ASCE/SEI 7-10 permits the use of auxiliary rational analysis methods, however such methods are out of the scope of this project. ASCE/SEI 7-10 Table 12.6-1 provides guidance on analysis procedure selection. In general, this selection is based on seismic design category, structural system, dynamic properties, and structural regularity.

Table 3 lists the horizontal and vertical irregularities in the archetype structure in accordance with ASCE/SEI 7-10 Table 12.3-1 and Table 12.3-2. In order to exclusively use the ELF method, the structure must not exhibit specific structural irregularities, and also must meet size limitations. The archetype structure exceeds the 2 story (above grade) requirement, but is within the 160 foot height restriction. As shown in Table 3, no irregularities exist in the structure, and therefore it is permissible by code to design the structural using only the ELF method. However, as the ELF method typically results in conservative designs, this research will use both the ELF method and the MRSA method in order to produce a more

efficient design. The THA method also provides a more representative analysis model of ground motions, however due to the simplicity of the structure, this method would be unlikely to produce a largely more efficient design when compared with the MRSA method.

Table 3. Horizontal and Vertical Irregularities

1. Reference Appendix A for supporting calculations

ASCE/SEI 7-10 also provides load combination requirements for seismic design. Pertinent combinations include:

- $(1.2 + 0.2S_{DS})D + \rho Q_E + 0.5L$
- $(0.9 - 0.2 S_{DS})D + \rho Q_E$

Where,

- S_{DS} = Short-period design spectral acceleration
- S_{D1} = 1-second design spectral acceleration
- D = Dead Load
- L = Live Load
- Q_E = Effect of horizontal seismic forces
- ρ = Redundancy Factor

2.3.1. Equivalent Lateral Force Method

The general process of the ELF method includes calculating equivalent lateral static forces that represent the inertial forces that a structure would experience during a seismic event. These forces are derived using a seismic response coefficient, based on seismic design parameters, that is applied to the seismic weight of the structure. This overall base shear is then distributed vertically based on the distribution of seismic weight at each level. The structure must be able to resist seismic forces in any direction, and therefore typically the ELF distribution is applied in both orthogonal directions. If orthogonal lateral resisting systems share components, concurrent loading is required. For this investigation, the structure was not analyzed for strength using the ELF method, as a more efficient design can typically be obtained by using the MRSA method. However, as required by ASCE/SEI 7-10, the ELF method is used in calculating maximum drifts. Calculations concerning the equivalent lateral static loads and distributions can be found in Appendix A.

As noted in ASCE/SEI 7-10 Section 12.12.1, story drifts and displacements may be calculated using either the ELF or MRSA methods. However, as drifts and displacements are of high importance to the integrity of a structure, the ELF method is used to provide a conservative approximation. In order to calculate these deformations, both inherent and accidental torsion must be accounted for in the model. Inherent torsion is that torsion which comes from forces acting through the center of mass of the structure being resisted by forces located at the center of rigidity. As the archetype structure is symmetric in both directions, there is no inherent torsion. Accidental torsion typically is caused by a number of factors, most commonly the variance in propagation of seismic waves, and the unlikelihood of a perfectly constructed symmetric structure. Accidental torsion is accounted for by applying a torsion equal to a 5% eccentricity of shear loading, to the center of mass of the structure. Calculations concerning torsional effects can be found in Appendix A.

The results of the model, including the effects of torsion, are used to calculate the existence of torsional irregularities, as well as any required accidental torsion amplification. If amplification is required, the model must be analyzed again for finalized deformations. This process theoretically can be iterated a large number of times until the amplification factor converges to unity, however typical design practice implements only one iteration. Additionally, if design uses the MRSA method, drifts are required to be scaled by 85% of the ratio of the ELF base shear to the MRSA base shear. This is required only if the MRSA base shear is less than 85% of the ELF base shear. Finally, drifts must be multiplied by the deflection amplification factor, which is based on the lateral system type. For the archetype structure, drift ratios are limited to 2%, as required by ASCE/SEI 7-10 Table 12.12-1. Figure 3 shows the calculated story drifts for the archetype structure in each orthogonal direction. Figure 4 shows the calculated story deflections for the archetype structure in each orthogonal direction. Calculations for story drift and MRSA scaling factors can be found in Appendix A.

Figure 3. Archetype Structure Story Drift Ratios

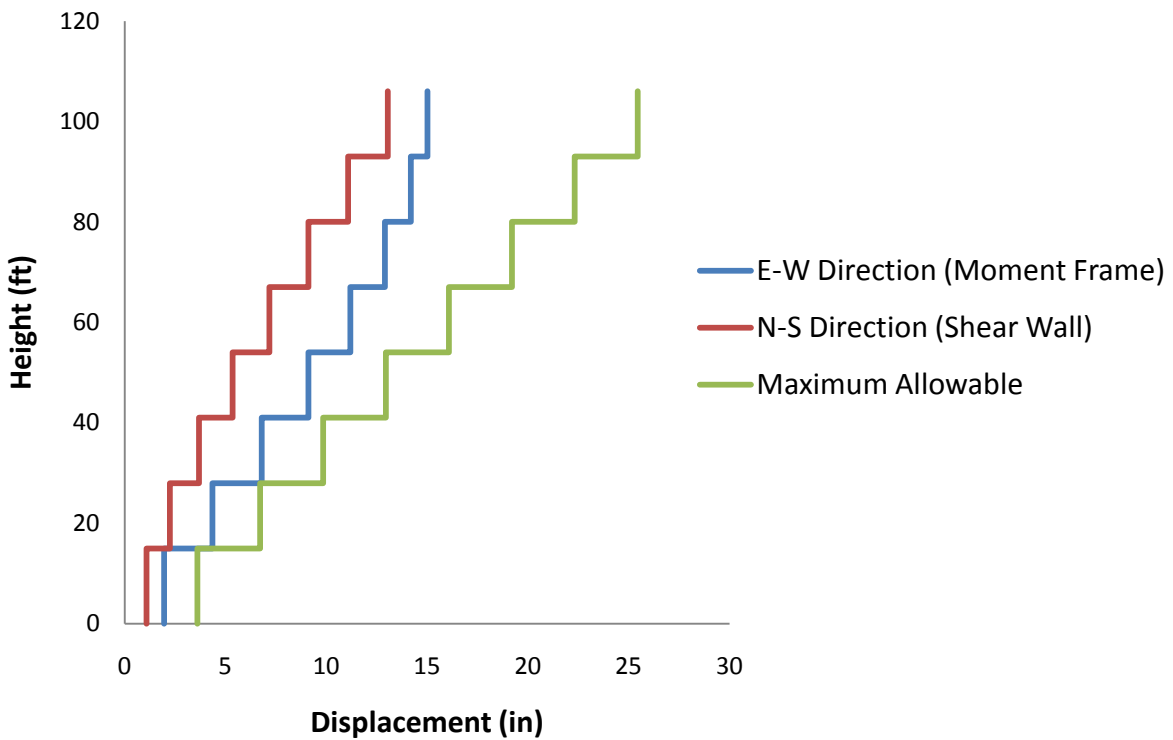

Figure 4. Archetype Structure Story Deflections

2.3.2. Modal Response Spectrum Analysis Method

The MRSA method models the actions on a structure from seismic events more realistically than the ELF method through the use of ground motions; this typically results in a more accurate depiction of the response of the structure to seismic loading. Demands from the MRSA method are the result of inertial forces in the structure that develop due to the ground motion. The general theory behind this method can be related to basic structural dynamics of multi-degree of freedom systems. The structure typically has as many mode shapes as levels, however only a relatively small percentage of the mass participates in any mode other than the fundamental mode. ASCE 7-10 Section 12.9.1 requires that a structure model includes a sufficient number of modes in order to reach a mass participation factor of at least 90%. This ensures that the majority of the actions from seismic activity are adequately incorporated. Calculations indicating compliance with this requirement can be found in Appendix A.

As mentioned, in this investigation the MRSA method is used to determine the strength demands on the structure, as it can typically provide more efficient designs. Moment, shear, and axial diagrams for a typical moment frame, and a typical exterior and interior shear wall can be found in Appendix B. In support of the decision to use the MRSA method for strength demands, a story shear comparison, found in Figure 5, clearly indicates the lower demands on the structure using the MRSA method.

Figure 5. Story Shear Comparison between ELF and MRSA Method

2.3.3. Redundancy Factor

ASCE/SEI 7-10 provides additional requirements which take into account the redundancy in the lateral system of a structure. These requirements are used to ensure that in the event of a lateral system component failure, the structure can continue to support lateral loads for the remainder of the seismic

(or wind) event and until repairs can be made. For this reason, in Seismic Design Categories D and above, ASCE/SEI 7-10 Section 12.3.4 requires that a redundancy factor be applied to the lateral resisting systems of a structure. This redundancy factor, ρ , is permitted to be taken as unity for the specific conditions noted in ASCE/SEI 7-10 Section 12.3.4.1. Otherwise, ASCE/SEI 7-10 Section 12.3.4.2 requires that ρ equal to 1.3 be applied to all lateral resisting systems. As an exception, the code provides guidance on calculating the inherent redundancy in a structure; if the structure is adequately redundant, ρ is permitted to be taken as unity. This analysis ensures that the loss of a single moment frame bay or shear wall segment does not result in the loss of more than 33% of the story strength, nor does the resulting structure have an extreme torsional irregularity. Calculations regarding structure redundancy in each direction can be found in Appendix A, which indicate that ρ may only be taken as unity for the moment frames.

2.3.4. P-Delta Effects

P-Delta effects are the additional stresses on a system component due to gravity loads acting on the deformed configuration of a system. These effects can be captured either through a nonlinear analysis, or a simplified linear analysis which implements geometric adjustments that represent these deformations. A full analysis must include P-Delta effects as they can greatly increase the stresses in a system component. However, ASCE/SEI 7-10 Section 12.8.7 permits P-Delta effects to be neglected in the case where the stability coefficient, θ , is less than or equal to 0.10. Design calculations, found in Appendix A, indicate that P-Delta effects need not be considered for the archetype structure.

2.4. Archetype Structure Design Modeling

ASCE/SEI 7-10 Section 12.7.3 provides guidance on structural modeling. In general, a model must account for the stiffness and strength of structural components, including the reduced stiffness of reinforced concrete components resulting from cracking. Additionally, force distributions, deformations, and masses (for the MRSA method) must be included in the model. The code permits 2-Dimensional models of lateral systems if certain irregularities do not exist, however in order to capture a more accurate representation, the archetype structure is modeled as a 3-Dimensional structure. SAP2000 (CSI, 2010) structural analysis software is used in this investigation.

2.4.1. Structural Component Modeling

Stiffness and strength of components is important in providing an accurate model of the archetype structure. Material properties, section properties, flanged construction, and anticipated cracking are all important factors in modeling of component stiffness. Theoretically, the cracked section of a concrete member varies along the span with the moment demand. However, modeling such a variance is difficult for large scale models, and so various stiffness reduction factors are used for different structure components. Reduction factors used in the modeling of the archetype structure were adopted from FEMA P752. Table 4 shows the various factors corresponding to different components. Flanged construction, or T-Beams, for the archetype structure are modeled using major axis moment of inertia scaling factors in SAP2000. Beams are modeled as rectangular sections and therefore simple calculations, found in Appendix A, are required to obtain a scale factor that provides a rectangular section with the equivalent T-Beam moment of inertia.

Table 4. Stiffness Reduction Factors for Structural Modeling

	Beams	Columns	Walls
Stiffness Reduction	$0.5 * E I_g$	$0.7 * E I_g$	$0.8 * E I_g$

Strength is not explicitly modeled in the SAP2000 model. The model is, however, used to determine strength requirements for various components. As this investigation does not make use of the design capabilities of SAP2000, such strength requirements are used in the design spreadsheet during the design process. More information on the design of structural components can be found in Section 2.5.

2.4.2. Mass Modeling

Mass modeling of structures can be accomplished through many different methods. Each method has strengths and weaknesses, such as efficiency, accuracy, and ease of use. Two methods are explored to examine the possibility that a sufficiently accurate, yet simple method is employed. The archetype structure is modeled using both a “smeared mass” approach, and a “lumped mass” approach. These methods are explained in more detail below, however the final model uses the smeared mass approach to achieve the most accurate results.

2.4.2.1. Smeared Mass Approach

In this more complex method, the mass is distributed over the entire floor system at each level. Similarly sized floor (shell) elements are used to discretize the floor system. The option to refine the mesh is at the discretion of the designer, however it is prudent to place nodes at all of the columns within the structure so that the area masses are lumped directly to each column. Smeared area masses are then lumped at the columns associated with each floor element. Additionally, the seismic contribution of non-structural elements, such as curtain walls, is linearly distributed (using vertical tributary area) at the perimeter frame or wall elements of the structure. From this point, it is simply a matter of running a multi degree of freedom dynamic model of the structure (in this case, SAP2000 was used for this analysis) to obtain the structure modal response.

In this method, all lateral resisting members, including columns, beams, and structural shear walls, are assigned a self mass. This is done to ensure the center of mass of these elements is in agreement with the actual structure. Floor elements and secondary framing is assigned a zero mass, as additional area masses will be manually added to accommodate for both the self mass and superimposed seismic masses (such as roofing, utilities, etc). Lastly, the ground floor and below are assigned a zero mass, as these elements are assumed to experience relatively small displacements, and therefore do not significantly contribute to the modal response of the building. A more in depth look into the effects of the below ground levels (and site conditions) to the modal response of the structure is out of the scope of this project.

2.4.2.2. Lumped Mass Approach

The lumped mass approach takes a more simplified approach than in the smeared mass approach. In this method, the full seismic mass of each floor is taken as a single lumped mass located at the center of mass of each floor. To retain torsional effects, this lumped mass is distributed amongst the corner

columns. In this method, all elements, including structural shear walls, beams, columns, and curtain walls are assigned a zero mass. In this process, special attention must be paid in calculating the correct total mass at each level to ensure an accurate model. Note that this does not reduce the model to a simple stick model, as the structure geometry as well as the various element stiffnesses are still included in the model. Keeping with consistency, the model is analyzed using SAP2000 modal analysis.

2.5. Lateral System Design

The lateral design of a structure is based typically on wind and seismic forces. Although this investigation is intended to be a review of seismic design and assessment methods, it is pertinent to examine the behavior of the structure under design wind loads to ensure that the seismic demands control the lateral system design. ASCE/SEI 7-10 Chapter 26 and 27 provide requirements for design wind forces and directional combinations. Calculations using the Directional Method can be found in Appendix A. Figure 6 shows a comparison between story shears resulting from MRSA and wind analyses. Clearly, wind demands do not control the design of the archetype structure.

Figure 6. Story Shear Comparison between Seismic and Wind Demands

Additionally, in an effort to represent a viable gravity system, nominal calculations were made to ensure secondary framing members, including the slab, are capable of supporting the gravity loads of each floor.

2.5.1. Special Reinforced Concrete Moment Resisting Frame Design

The general lateral design procedure for the moment frame adheres to the capacity design philosophy. Unless otherwise specified, materials are manufactured with strengths at or above the specified minimums. This increased strength (referred to in design as “probable strengths”) can cause a component to yield in an unanticipated mode, such as shear. Shear is not a preferred failure mode as it is a brittle failure (non-ductile) and typically occurs without warning.

Design of the moment frame is also based on the strong column weak beam (SCWB) premise. It is important to instigate this principle as it provides a level of protection against catastrophic failure in the event of a simple component failure. To prevent this type of failure, columns are designed to resist the full flexural capacity of the beams which frame into the joint. This ensures that the column will not fail prior to, or concurrently with the beam. The SCWB method is prescribed for design through the requirements in ACI 318-08 Chapter 21. Moment, shear, and axial diagrams used in design from MRSA analysis can be found in Appendix B. Figure 7 shows a typical layout elevation for moment frames, and Figure 8 shows typical moment frame reinforcing layout with member cross sections. Additionally, Figure 9 is a moment frame elevation which indicates various flexural, shear, and axial demand to capacity ratios. As the building is symmetric, this elevation represents a typical structural design for the two moment frames.

Figure 7. Typical Moment Frame Elevation

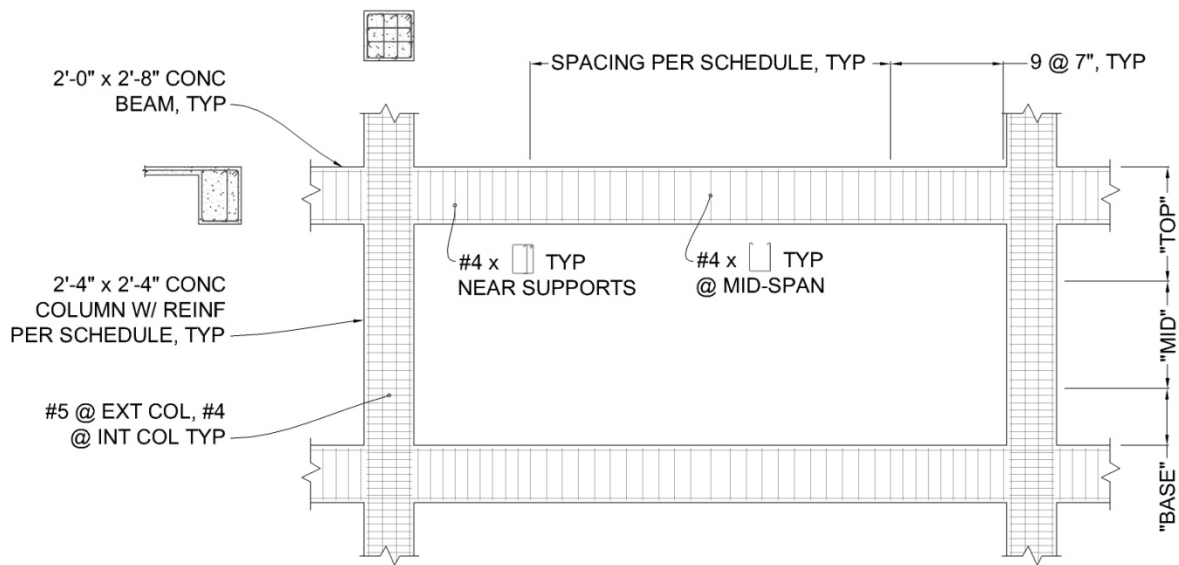

Figure 8. Typical Moment Frame Bay Reinforcing Layout

Moment frame beams in the archetype structure are designed with flexural reinforcing capable of resisting moment demands from MRSA. Specified material strengths are used to ensure that the minimum capacity of the beam is adequate to resist such demands. The probable flexural strength of the beam is then used to calculate the probable shear demand at the onset of flexural yielding. This is done to satisfy capacity design principles, which ensure flexural yielding prior to shear failure. Figure 10 shows the reinforcing schedule for the moment frame beams. Supporting calculations for moment frame beams can be found in Appendix A.

To provide SCWB action, the probable flexural strengths of adjacent beams are used to determine the flexural demands on the columns. As columns experience both flexural and axial demands, interaction analysis is used to determine the adequacy of column reinforcement. Interaction diagrams for all columns are calculated using PCA Column, and can be found in Appendix C. These interaction diagrams represent the various axial and flexural demands on all columns of a certain reinforcing pattern. Similar to the beams, the shear demand on the columns is based on the probable onset of flexural yielding in the columns. Figure 11 provides transverse reinforcing information for the moment frame columns. Corner columns along the moment frame have (12) #8 longitudinal bars while interior edge columns have (10) #10 longitudinal bars. Supporting calculations for the moment frame columns can be found in Appendix A.

Figure 9. Typical Moment Frame Demand Capacity Ratios

The joints at which the beams and columns intersect are designed for a shear demand representing the onset of flexural yielding in adjacent framing members. As joints are integral in providing support of gravity loads, this component is typically designed not to fail until the ultimate collapse of the structure. Supporting calculations for the moment frame joints can be found in Appendix A.

2.5.2. Special Reinforced Concrete Shear Wall Design

Design of the shear walls and corresponding boundary columns is based on ACI 318-08 Chapter 21 provisions. Shear reinforcement is calculated using the shear demand results from the MRSA. Shear reinforcing is based on developing adequate shear capacity, calculated using ACI 318-08 Equation 21-7.

Design for flexural and axial loads is similar to that of the moment frame columns, in that interaction diagrams are required to ensure adequate capacity. Again, PCA Column is used for this analysis, and representative design interaction diagrams for the base level of each shear wall can be found in Appendix C.

Boundary elements are used to ensure adequate ductility in the shear wall. Two methods are prescribed in ACI 318-08 Section 21.9.6.2 and Section 21.9.6.3 to calculate where they are required. The second method, a stress-based procedure, is used in this investigation. By analysis, neither the interior or exterior shear walls require additional boundary element reinforcing.

Design drawings for exterior and interior shear walls can be found in Figure 12 and Figure 13, respectively. Exterior and interior shear wall elevations indicating demand to capacity ratios are shown in Figure 14. Support calculations for shear reinforcing in the wall panel, flexural and shear reinforcing in the boundary columns, and adequacy of boundary elements can be found in Appendix A.

3. ARCHETYPE STRUCTURE ASSESSMENT

Seismic assessment of existing structures is important to maintain a confident level of safety. ASCE/SEI 41-06 provides guidance on analysis methods and acceptance criteria for both assessment and rehabilitation. The archetype structure is completely known, and therefore analysis throughout this section uses a knowledge factor of 1.0, and all material testing requirements are not applicable. As this investigation is intended to be a general evaluation of the assessment of new construction methods using the existing building criteria in ASCE/SEI 41-06, all prescribed analysis methods are examined.

3.1. Performance Objectives and Seismic Hazard Definitions

ASCE/SEI 41-06 is based on the principle of performance objectives, specifically for rehabilitation projects. These performance objectives include: Immediate Occupancy (IO), Life Safety (LS), and Collapse Prevention (CP). ASCE/SEI 41-06 Section C1.5.1.1 describes the IO objective as retention of lateral and gravity system stiffnesses and strengths, and relatively minor structural damage for which repairs are not required prior to re-occupancy. ASCE/SEI 41-06 Section C.1.5.1.3 describes the LS objective as severe structural damage, however partial or full collapse is not imminent. Additionally, the LS objective does include the possibility of earthquake related injuries, however these injuries are not expected to be life-threatening. Lastly, ASCE/SEI 41-06 Section C.1.5.1.5 describes the CP objective as the state at which partial or full collapse of the structure is imminent. Structural components have significant reductions in stiffness and strength, and the risk of injury due to falling components is high. The structure may also be impractical to repair.

The performance objectives in ASCE/SEI 41-06 are defined seismically by probabilistic earthquake levels. Probabilistic earthquake hazards are defined using the desired probability of exceedance and minimum expected structure life. Refer to ASCE/SEI 41-06 Section 1.6 for more information regarding probabilistic earthquake hazards. As mentioned earlier, the spectral accelerations, S_s and $S_{1,}$ are defined at the D_{MAX} level for the archetype structure. ASCE/SEI 41-06 Section 1.6 provides guidance on calculating the various seismic hazards for corresponding performance objectives. Contrary to ASCE/SEI 7-10, ASCE/SEI 41-06 denotes the design spectral response accelerations as S_{XS} and S_{X1} . Table 5 shows each performance objective, and the corresponding probability of exceedance and seismic hazard. Support calculations can be found in Appendix D.

Table 5. Performance Objective Seismic Hazards

	Probability of Exceedance	S_{XS} (g)	S_{X1} (g)
Immediate Occupancy	50% / 50 Year	0.633	0.367
Life Safety	10% / 50 Year	1.100	0.640
Collapse Prevention	2% / 50 Year	1.500	0.900

3.1.1. Response Spectrum

Development of the response spectrum is based on ASCE/SEI 41-06 Section 1.6.1.5. ASCE/SEI 41-06 uses a slightly different method for calculating a response spectrum as that found in ASCE/SEI 7-10. Figure 15

shows the calculated response spectrums for each performance objective. The response spectrum calculated using ASCE/SEI 7-10, found in Figure 1, is also plotted for comparison. Discussion of response spectrum methods and use is included later in this report.

Figure 15. ASCE/SEI 41-06 Performance Objective Response Spectrums

3.1.2. Time Histories

In addition to response spectrum analysis, complete ASCE/SEI 41-06 assessment requires the use of time history analysis. To maintain consistency, a set of 44 time history records defined in the FEMA P695 are used in analysis. These records are applied in analysis in each direction, using both maximum and minimum gravity load combinations. Each record is normalized and accompanied by a previously calculated response spectrum, with which a scale factor is determined for the specific record. Additionally, performance objective scale factors are calculated using these time history response spectrums and ASCE/SEI 41-06 calculated response spectrums shown in Figure 15. These scale factors are calculated by matching the average (Square Root of the Sum of Squares method) 1-second spectral accelerations of the time histories with the corresponding 1-second spectral acceleration of the target response spectrum. This scaled average, with the corresponding target response spectrum, is shown in Figure 16. Support calculations for time history record scaling can be found in Appendix F.

Figure 16. Time History Record Scaling

3.2. Linear Procedures

Linear procedures incorporate traditional linear stress-strain relationships for component strengths. For this reason, solely linear analysis can only accurately capture elastic behavior. As elastic behavior is an unrealistic design assumption for seismic design, adjustments are made to account for probable nonlinearities in the system. ASCE/SEI 41-06 linear procedures employ adjustment factors, m and J , for deformation-controlled and force-controlled actions, respectively, to account for these nonlinearities. Although this process is a simplification of complex behavior, it provides a good estimate for simple and regular structures. For this reason, ASCE/SEI 41-06 Section 2.4.1.1 provides various restrictions on use of linear procedures. As mentioned previously however, the archetype structure is assessed using all methods prescribed in ASCE/SEI 41-06.

The archetype structure uses the same model for all linear procedures. The model accounts for both flexural, shear, and axial stiffness through the use of stiffness reduction factors prescribed in ASCE/SEI 41-06 Table 6-5. Table 6 summarizes ASCE/SEI 41-06 Table 6-5 with pertinent structural components. Due to the relatively low gravity loads, all moment frame are assigned flexural stiffness reduction factors equal to, or near, $0.3 \cdot E I_g$. Note that flexural stiffness reduction factors prescribed in ASCE/SEI 41-06 Table 6-5 are much less than those used in design.

Table 6. ASCE/SEI 41-06 Stiffness Reduction Factors

Component	Flexural Rigidity	Shear Rigidity	Axial Rigidity
-----------	-------------------	----------------	----------------

Beams	$0.3*EI_g$	$0.4*EA_w$	(-)
Columns ($P_g \geq 0.5*A_g*f_c'$)	$0.7*EI_g$	$0.4*EA_w$	$1.0*EA_g$
Columns ($P_g \leq 0.1*A_g*f_c'$)	$0.3*EI_g$	$0.4*EA_w$	$1.0*EA_g$
Walls	$0.5*EI_g$	$0.4*EA_w$	$1.0*EA_g$

ASCE/SEI 41-06 accounts for capacity design principles through the use of deformation-controlled and force-controlled actions. Typically ductile failure modes, such as flexural yielding in beams, are defined as deformation-controlled actions while brittle failure modes, such as shear in beams, are considered force-controlled. Component strengths are calculated using similar design principles as in design, however lower-bound and expected strengths are used for deformation-controlled and force-controlled actions, respectively. ASCE/SEI 41-06 Table 6-4 provides factors for use in calculating expected strengths. Component strengths, similar to design, are not explicitly modeled in SAP2000; demands calculated using SAP2000 are checked against calculated strengths. More information regarding deformation-controlled and force-controlled actions can be found in ACSE/SEI 41-06 Section 2.4.4.3.

ASCE/SEI 41-06 Section 3.2.5 requires that P-Delta effects be included in linear analysis. P-Delta effects are accounted for through the use of a “leaning” column and nonlinear static gravity loads in SAP2000. The “leaning” column does not contribute to the stiffness of the structure, nor does it develop any moment. Remaining gravity loads on the structure not resisted by the lateral systems are assigned to the “leaning” column.

3.2.1. Linear Static Procedure

3.2.1.1. Analysis Methodology

The general premise behind the linear static procedure (LSP) is similar to the equivalent lateral force method defined in ASCE/SEI 7-10 (reference section 2.3.1). ASCE/SEI 41-06 Section 3.3.1.3 defines a pseudo-lateral force distributed horizontally and vertically on the structure. Such factors as structure period, mass, and design spectral acceleration affect the magnitude of this pseudo-lateral force. Calculated base shears for corresponding performance objectives, compared with the design base shear (from MRSA), are shown in Table 7. The sizeable differences in base shear arise from the method with which the seismic coefficients are calculated. ASCE/SEI 41-06 does not account for lateral system ductility in calculations of the pseudo-lateral force while ASCE/SEI 7-10 does, through the use of R factors. Support calculations for Table 7 can be found in Appendix D.

Table 7. Linear Static Procedure and Design Base Shears

Direction	IO (kips)	LS (kips)	CP (kips)	Design (kips)
Moment Frame	1,520	2,652	3,729	412
External Shear Wall	1,755	3,063	4,307	571
Internal Shear Wall	1,622	2,831	3,980	571

The LSP also accounts for both inherent and accidental torsion, as defined in ASCE/SEI 41-06 Section 3.2.2.2. For 2-Dimensional models, torsion is accounted for by increasing the lateral forces by a η factor.

This η factor requires 3-Dimensional analysis that accounts for torsional effects, and represents the ratio of maximum displacement to average displacement of a floor. ASCE/SEI 41-06 is however not clear on torsion requirements when a low η factor is calculated. ASCE/SEI 41-06 Section 3.2.2.2.3 indicates that increased forces and displacements due to torsion are not required when the η factor at each level is less than 1.1, however ASCE/SEI 41-06 Section 3.2.2.2.6 states that torsional effects for 2-Dimensional models should be calculated and incorporated. As a conservative approach, this investigation accounts for torsional effects in the 2-Dimensional models, though the η factor for the moment frames and interior shear walls is less than 1.1 at each level. Support calculations for horizontal torsion effects can be found in Appendix D.

Acceptance criteria for the LSP are based on demand and capacity principles. ASCE/SEI 41-06 Section 3.4.2.2 provides demand-capacity requirements for both deformation-controlled and force-controlled actions. In general, capacities of deformation-controlled components are increased by the m factor, while seismic demands of force-controlled components are decreased by the J factor.

3.2.1.2. Results

Results from the LSP clearly indicate inconsistencies between design and assessment. In general, component failures occur in the lower levels of the structure for all performance objectives. Typically, the magnitude and rate of occurrence of failure increases with more stringent performance objectives.

In moment frame beams, positive moment capacity is the most common failure. In general, these failures occur with demand to capacity ratios (DCR) ranging from around 1.25 at the IO performance objective, to 2.0 at the CP performance objective. This could be due to the significantly higher lateral loads calculated using ASCE/SEI 41-06. In design, positive moment demand at beam ends is typically lower than negative moment demand because the gravity loads produce relatively significant increases in negative moment demand. However, when lateral loads represent such a large percentage of the total demands, the positive and negative moment demands have similar magnitudes. This results in failure in positive flexure, as the positive moment capacity of the beams is lower than that of the negative moment capacity. Additionally, due to the large increase in lateral load, shear failures occur for all performance objectives, typically in end bays on lower levels. Typically, DCR's for shear failure ranges from approximately 1.0 at the IO performance objective to 2.0 at the CP performance objective.

In moment frame columns, the occurrence of failure in flexure is low at all performance objectives. However, it is important to note that edge columns experience net tension under the comparatively large lateral loads, and therefore interaction failure in these columns is common. Column shear and joint shear demands are adequately resisted throughout all performance objectives.

Under ASCE/SEI 41-06 loading, both interior and exterior shear walls fail in flexural-axial interaction at the lower levels for all performance objectives. The cause of these failures is likely the reduced gravity load combinations prescribed by ASCE/SEI 41-06 in combination with much higher lateral demands. Typically, shear walls that exhibit flexural-axial interaction failures have DCR values ranging between 1.0 and 1.5 for all performance objectives. Shear walls are adequate in shear capacity for all performance objectives.

A representative moment frame elevation is shown in Figure 17, indicating IO performance objective failures. Similarly, Figure 19 represents failures in interior and exterior shear walls under the IO performance objective. A key for moment frame elevations, and similar subsequent elevations, is shown in Figure 18. A key for shear wall elevations, and similar subsequent elevations, is shown in Figure 20. Similar elevations for LS and CP objectives can be found in Appendix E. Support calculations for all lateral systems under LS and CP performance objectives can be found in Appendix D.

3.2.2. Linear Dynamic Procedure

3.2.2.1. Analysis Methodology

The linear dynamic procedure (LDP) incorporates the use of both modal response spectrum analysis and time history analysis. Similar to the LSP, the LDP imposes linear elastic demands on the structure, and accounts for inelasticity through adjustment factors. This method provides a more accurate model of the motions that are experienced during a seismic event, however maintains simplifications to account for nonlinear response behavior.

Use of modal response spectrum analysis requires models that can sufficiently capture at least 90% of the participating mass of the structure. Maximum forces and displacements are combined using the complete quadratic combination, as permitted per ASCE/SEI 41-06 Section 3.3.2.2.3. The archetype structure is assigned a typical structure damping ratio of 5%, per ASCE/SEI 41-06 Section 1.6.1.5.3. Time history analysis employs the described set of time history records in Section 3.1.2. As permitted by ASCE/SEI 41-06 Section 3.3.2.2.4, the maximum response parameters, including forces and displacements, are the average of those produced by each record. Records are implemented in SAP2000 using modal analysis of linear, transient time histories. For linearly defined loading, the total response of a member or structure to multiple load types (i.e. gravity and seismic) is the sum of the responses of each load type. For this reason, order of action does not affect the total response of the structure, and therefore is not used in the LDP.

Table 8 and Table 9 show the base shears for the various performance objectives using modal response spectrum analysis and time history analysis, respectively. As shown, the base shear values used for various performance objectives are much higher than those used in design. This is a result of the differing methods used to define seismic hazard and response in ASCE/SEI 7-10 and ASCE/SEI 41-06. ASCE/SEI 7-10 reduces the base shear based on the type of lateral resisting system used; this reduction is a function of the ductility of the lateral system. On the contrary, ASCE/SEI 41-06 uses system ductility to increase the capacity of various components. This discrepancy presents a difficult comparison for base shear between the two methods, although also provides a good explanation for the varying results obtained using ASCE/SEI 7-10 design and ASCE/SEI 41-06 assessment.

Table 8. Linear Dynamic Procedure (Response Spectrum Analysis) and Design Base Shears

Direction	IO (kips)	LS (kips)	CP (kips)	Design (kips)
Moment Frame	1,748	3,049	4,284	412
External Shear Wall	1,679	2,927	4,087	571
Internal Shear Wall	1,562	2,722	3,799	571

Table 9. Linear Dynamic Procedure (Time History Analysis) and Design Base Shears

Direction	IO (kips)	LS (kips)	CP (kips)	Design (kips)
Moment Frame	1,499	2,617	3680	412
External Shear Wall	1,288	2,249	3,158	571
Internal Shear Wall	1,188	2,074	2,913	571

Additionally, as required by ASCE/SEI 41-06, torsional effects are included in analysis by amplifying maximum forces and displacements by the maximum η factor, similar to the LSP. Acceptance criteria for the LDP are similar to those of the LSP.

3.2.2.2. Results

Moment frame assessment is considerably better using the modal response spectrum analysis method when compared with the LSP. At the IO performance objective, beams, columns, and joints are adequate in resisting demands on the structure, with the exception of first level edge columns. These specific columns are inadequate in flexural-axial interaction, likely due to the large overturning forces that result in net tension in the columns. Similar to the LSP, beams fail in flexure at the LS and CP performance objectives, however at a considerably lower rate. Columns also experience flexural-axial interaction failures at the LS and CP performance objectives, a likely result of lower axial forces caused by high lateral demands. Again, joint shear is adequately resisting in the moment frames for all performance objectives. Comparatively, time history analysis results in an increase in failure occurrence in beams and columns. The failures themselves, however, are similar to those found in modal response spectrum analysis.

Interior shear walls exhibit flexural-axial interaction failures within the first three floors of the archetype structure under response spectrum analysis demands for various performance objectives. However, such failures do not occur in exterior shear walls, or when analyzed using time history analysis demands. Shear failures do not occur in any shear walls under either analysis. It is important to note the correlation between performance of shear walls and moment frames under response spectrum analysis and time history analysis. Both lateral systems met a higher percentage of ASCE/SEI 41-06 acceptance criteria using time history analysis as compared with response spectrum analysis. This can also be seen through base shear comparisons, found in Table 8 and Table 9.

Representative moment frame elevations indicating IO performance objective failures for response spectrum analysis and time history analysis are shown in Figure 21 and Figure 22, respectively. Figure 23 is a representative shear wall elevation at the IO performance objective using response spectrum analysis. As no failures, at the IO performance objective level, occur during time history analysis, an elevation is unnecessary. Similar elevations for LS and CP objectives can be found in Appendix E. Support calculations for all lateral systems under LS and CP performance objectives can be found in Appendix D.

3.3. Nonlinear Procedures

Contrary to linear procedures, nonlinear procedures provide a much more accurate depiction of structure behavior for inelastic response. As opposed to approximating nonlinearity through the use of stiffness modifiers and capacity adjustment factors, nonlinear procedures model the inelastic stress-

resultant (i.e. load-displacement or moment-curvature) relationships for each component anticipated to experience yielding. Such relationships include strain-hardening and strain-softening properties for the specific material. Although materials such as concrete and steel typically exhibit nonlinear strain-hardening and strain-softening properties, linear approximations of these regions can be made to significantly reduce calculation intensity while maintaining accuracy. As noted in ASCE/SEI 41-06 Section 6.3.1.2.2, reinforced concrete behavior can be modeled using a force-deformation curve defined in ASCE/SEI 41-06 Figure 6-1, as shown in Figure 24. This curve is normalized by the yield force, although this is not necessary. Additionally, the parameters a , b , and c , are limits defined in ASCE/SEI 41-06.

Figure 24. Typical Force-Displacement Curve for Reinforced Concrete

For both moment frames and shear walls, major axis flexural hinges are used to model the nonlinear behavior of the archetype structure. To provide a more accurate model of nonlinear behavior, columns and shear walls should employ interaction hinges, which are capable of adjusting inelastic stress-strain relationships based on levels of axial load. ASCE/SEI 41-06 does indicate that flexural-axial interaction should be accounted for, including varying axial demand, although no clear guidance is provided. For this reason, average gravity loads are used to define inelastic stress-strain relationships for a constant axial load, which is then used to define the corresponding flexural hinges. This assumption is based on methods used in FEMA P695. Although this does not account for the axial load produced by lateral loads, it provides, for the most part, a conservative approximation of the flexural behavior.

Nominal shear wall and column interaction diagrams are calculated using PCA Column, although the traditional moment-curvature method is used in calculating yielding interaction diagrams. Concrete strength used in these calculations accounts for confined and unconfined strengths through the use of the Hognestad parabola. An isotropic hardening hysteresis model is used for simplicity, although a more detailed model accounting for stiffness degradation, such as the Takeda model, could be used to gain more behavioral accuracy. Additionally, shear wall models for nonlinear procedures are simplified as

multi-degree of freedom stick models. Each stick element represents a wall segment for a given level, and incorporates stiffness and mass properties that resemble the actual shear wall. In order to develop a more accurate model of the shear walls, a fiber model is required, which is out of the scope of this investigation.

Although the flexural hinges replace the use of approximate stiffness reduction factors, reductions in stiffness are required where hinges are not anticipated to occur as these areas still experience cracking. Guidance for defining this stiffness reduction is not clearly prescribed in ASCE/SEI 41-06, although practical estimates are permitted. For modeling purposes, similar stiffness reductions as those used in design are assigned to beams, columns, and shear walls in the archetype structure in order to account for component cracking.

For nonlinear procedures, connection behavior is modeled implicitly using provisions in ASCE/SEI 41-06 Section C6.4.2.2.1. Inherently, actual rotations cannot be directly calculated using these implicit models, as they use either 100%, 50%, or 0% rigidity. In order to capture joint rotations directly, explicit models incorporating rotational springs, or a similar method, are required. Results from linear procedures indicate joints are well within the prescribed limits and therefore this investigation does not examine the adequacy of joints using nonlinear methods.

Similar to linear procedures, P-Delta effects are required to be included in nonlinear procedures. Again, “leaning” columns and nonlinear gravity loads are used to account for P-Delta effects in the archetype structure. However, during analysis of the archetype structure under the nonlinear static and nonlinear dynamic procedures, convergence problems were encountered in the model that could only be immediately resolved by neglecting P-Delta effects. It is important to note, however, that P-Delta effects increase the stresses on a system, and therefore would produce larger deformations. As this investigation aims to review the assessment methods in ASCE/SEI 41-06, failures that neglect P-Delta effects represent a minimum collection of failures.

3.3.1. Nonlinear Static Procedure

3.3.1.1. Analysis Methodology

The nonlinear static procedure (NSP), also known as “pushover analysis”, combines simplistic loading mechanisms with complex modeling parameters to approximate the response of a structure. The premise behind the NSP uses incremental displacement controlled loading up to a specific target displacement. Preliminary structure pushover analysis is required to calculate these specific target displacements. From this analysis, an idealized force-displacement curve is derived based on provisions in ASCE/SEI 41-06 Section 3.3.3.2.5. This idealized force-displacement curve is used in determining the effective fundamental period of the structure in each direction. As the response of the structure throughout the elastic range is linear, the effective fundamental period may be taken as equal to the elastic period from modal analysis. Figure 25 and Figure 26 show pushover analyses for the moment frame and shear walls, respectively, which clearly indicate the linear elastic range of the lateral systems.

Figure 25. Pushover Curve for Moment Frames

Figure 26. Pushover Curve for Exterior and Interior Shear Walls

Target displacements for various performance objectives are based on spectral accelerations and effective fundamental period. Additionally, a modification factor, C_o , is used to relate the spectral displacement of an equivalent single-degree of freedom system to roof displacement of the structure multi-degree of freedom system. Target displacements are applied to a control node, which is located at the center of mass of the roof of the structure. Additionally, ASCE/SEI 41-06 Section 3.3.3.2 requires the structure to be loaded to 150% of the target displacement to investigate probable behavior under extreme seismic conditions. This is generally applied to rehabilitation design to verify that a structure will not collapse under extreme loading, and therefore is not included in the archetype structure assessment. It is important to note, however, that the moment frame exhibits a collapse mechanism at approximately 55 inches, which is less than the 150% target displacement of 60 inches. This is an example of why structures are required to be analyzed beyond the calculated target displacements. Table 10 shows the calculated target displacements for each lateral resisting system at various performance objectives. During analysis, these target displacements are also increased by the maximum η factor in order to account for torsional effects. Support calculations for target displacements can be found in Appendix D.

Table 10. Target Displacements for Lateral Systems

System	IO (in)	LS (in)	CP (in)
Moment Frame	16.3	28.5	40.1
External Shear Wall	6.4	11.1	15.7
Internal Shear Wall	5.9	10.3	14.5

Under the target displacements shown above, Table 11 shows the calculated base shears for the various performance objectives, and those calculated for design. Note that the performance objective base shears are similar because they correspond to the calculated target displacement for each objective.

Table 11. Nonlinear Static Procedure and Design Base Shears

Direction	IO (kips)	LS (kips)	CP (kips)	Design (kips)
Moment Frame	726	742	742	412
External Shear Wall	605	645	670	571
Internal Shear Wall	533	555	574	571

Acceptance criteria for the NSP are based on hinge rotation limits. ASCE/SEI 41-06 Chapter 6 includes various tables which provide guidance for calculating maximum rotations for various components, based on performance objective. Maximum allowable hinge rotations prescribed by ASCE/SEI 41-06, unless stated otherwise, refer to plastic hinge rotations, which are defined as any hinge rotation occurring after yielding.

3.3.1.2. Results

At target displacements, moment frame beams on the first and second levels of the archetype structure exceed the maximum allowable ASCE/SEI 41-06 hinge rotations for all performance objectives.

Additionally, beam hinge rotations on the third level exceed the maximum allowable rotations for the IO performance objective. These failures are likely caused by the relatively high variance in lateral loading used in ASCE/SEI 7-10 design, and ASCE/SEI 41-06 assessment. By analysis, beams at levels 6 and above remained elastic.

Plastic rotation in columns exceeds the maximum ASCE/SEI 41-06 hinge rotations in the moment frame columns located in the lower levels of the structure. Column deformation failures are limited to the top of level 3 columns and the bottom of level 1 columns. However, nearly all column hinges that did not exceed allowable rotation limits remained elastic for all performance objectives.

Analysis of both interior and exterior shear walls using the NSP indicate that all shear walls remain within the prescribed hinge rotation limits prescribed in ASCE/SEI 41-06 at all performance levels.

Figure 27 shows a representative moment frame elevation for performance level CP. The elevation indicates the various rotation range that each hinge reaches under the given target displacement. Additionally, Figure 28 and Figure 29 show the exterior and interior shear wall elevation, respectively, representing the CP performance objective. Specifically, yellow indicates that the hinge has rotated beyond the allowable ASCE/SEI 41-06 prescribed limit for the CP performance objective. Support calculations for the NSP can be found in Appendix D.

Figure 27. NSP Moment Frame Hinge Behavior (CP Objective)

Figure 28. NSP Exterior Shear Wall Hinge Behavior (CP Objective)

Figure 29. NSP Interior Shear Wall Hinge Behavior (CP Objective)

3.3.2. Nonlinear Dynamic Procedure

3.3.2.1. Analysis Procedure

The analysis procedure for the NDP is somewhat similar to the LDP, although only time history analysis is used. Response spectrum analysis uses modal coordinates to determine dynamic response in a system. However, in nonlinear behavior, the stiffness of a component varies with time and load intensity, often never regaining original elastic stiffness. Therefore by nature, the response spectrum method cannot be used to capture any nonlinear effects, which is why it is not used in the NDP. Time history analysis, however, imposes varying accelerations into the system over time, which allows nonlinear behavior in system components to propagate. Also, the method for implementing the time history records is different than that of the LDP. As nonlinear behavior is dependent on time and load intensity, it is sensitive to the order of loading. For this reason, gravity loads are applied to the model prior to running the time history records. As mentioned above, P-Delta effects are not included in the NDP due to convergence issues (reference section 3.3 for more information). Table 12 indicates the average base shears from time history analysis for various performance objectives, as well as those used in design.

Table 12. Nonlinear Dynamic Procedure and Design Base Shears

Direction	IO (kips)	LS (kips)	CP (kips)	Design (kips)
Moment Frame	802	943	*	412
External Shear Wall	847	1,122	1,465	571
Internal Shear Wall	745	1,017	1,282	571

*Note: Base shear results for the CP objective include collapse mechanisms, and therefore an average value is not representative of the analyzed results.

3.3.2.2. Results

Generally, moment frame beam and column plastic hinge rotations remain within prescribed ASCE/SEI 41-06 limits. However, certain time history records result in collapse mechanisms under the LS and CP performance objectives. Table 13 lists the various time history records which result in collapse of the structure.

Table 13. Time History Records causing Collapse Mechanisms

	LS Objective	CP Objective
Time History Record	9, 10, 17, 13, 15, 38, 41	3, 9, 10, 11, 13, 15, 17, 18, 20, 21, 24, 28, 29, 30, 31, 33, 34, 37, 38, 39, 41, 42

As shown, approximately 16% of LS and 50% of CP performance objective time history records result in collapse of the structure. When more than 7 records are used, ASCE/SEI 41-06 permits the design actions on a structure to be taken as the average of those actions caused by each time history record. By eliminating the specific time history records that result in a collapse mechanism, sufficient time history records remain that indicate the archetype structure moment frame meets the assessment criteria for the NDP. However, such records cannot be simply ignored, as they indicate the possibility of structure collapse. In an actual assessment or rehabilitation, greater consideration would be needed to ensure that the structure would not collapse under the specific suite of time histories used in analysis.

Plastic rotations occur in moment frame columns typically at the first and fourth levels. This indicates that the archetype structure deformation stems from multiple modes. As column reinforcing is typical throughout the height of the archetype structure, the column hinge locations are not a function of differing reinforcement patterns. Figure 30 and Figure 31 show bottom and top of column plastic hinge rotations at various performance levels, respectively. Column hinge numbers are ordered in ascending floor level, for grids A through F. Additionally, these figures indicate the maximum and minimum hinge rotations. The first and fourth floor mechanisms can be clearly seen in Figure 30. Both figures represent time history records which do not result in collapse mechanisms. Acceptance criteria for each performance objective are shown as dashed lines.

Figure 30. Bottom of Column Plastic Hinge Rotations

Note: Time history records resulting in collapse mechanisms not shown.

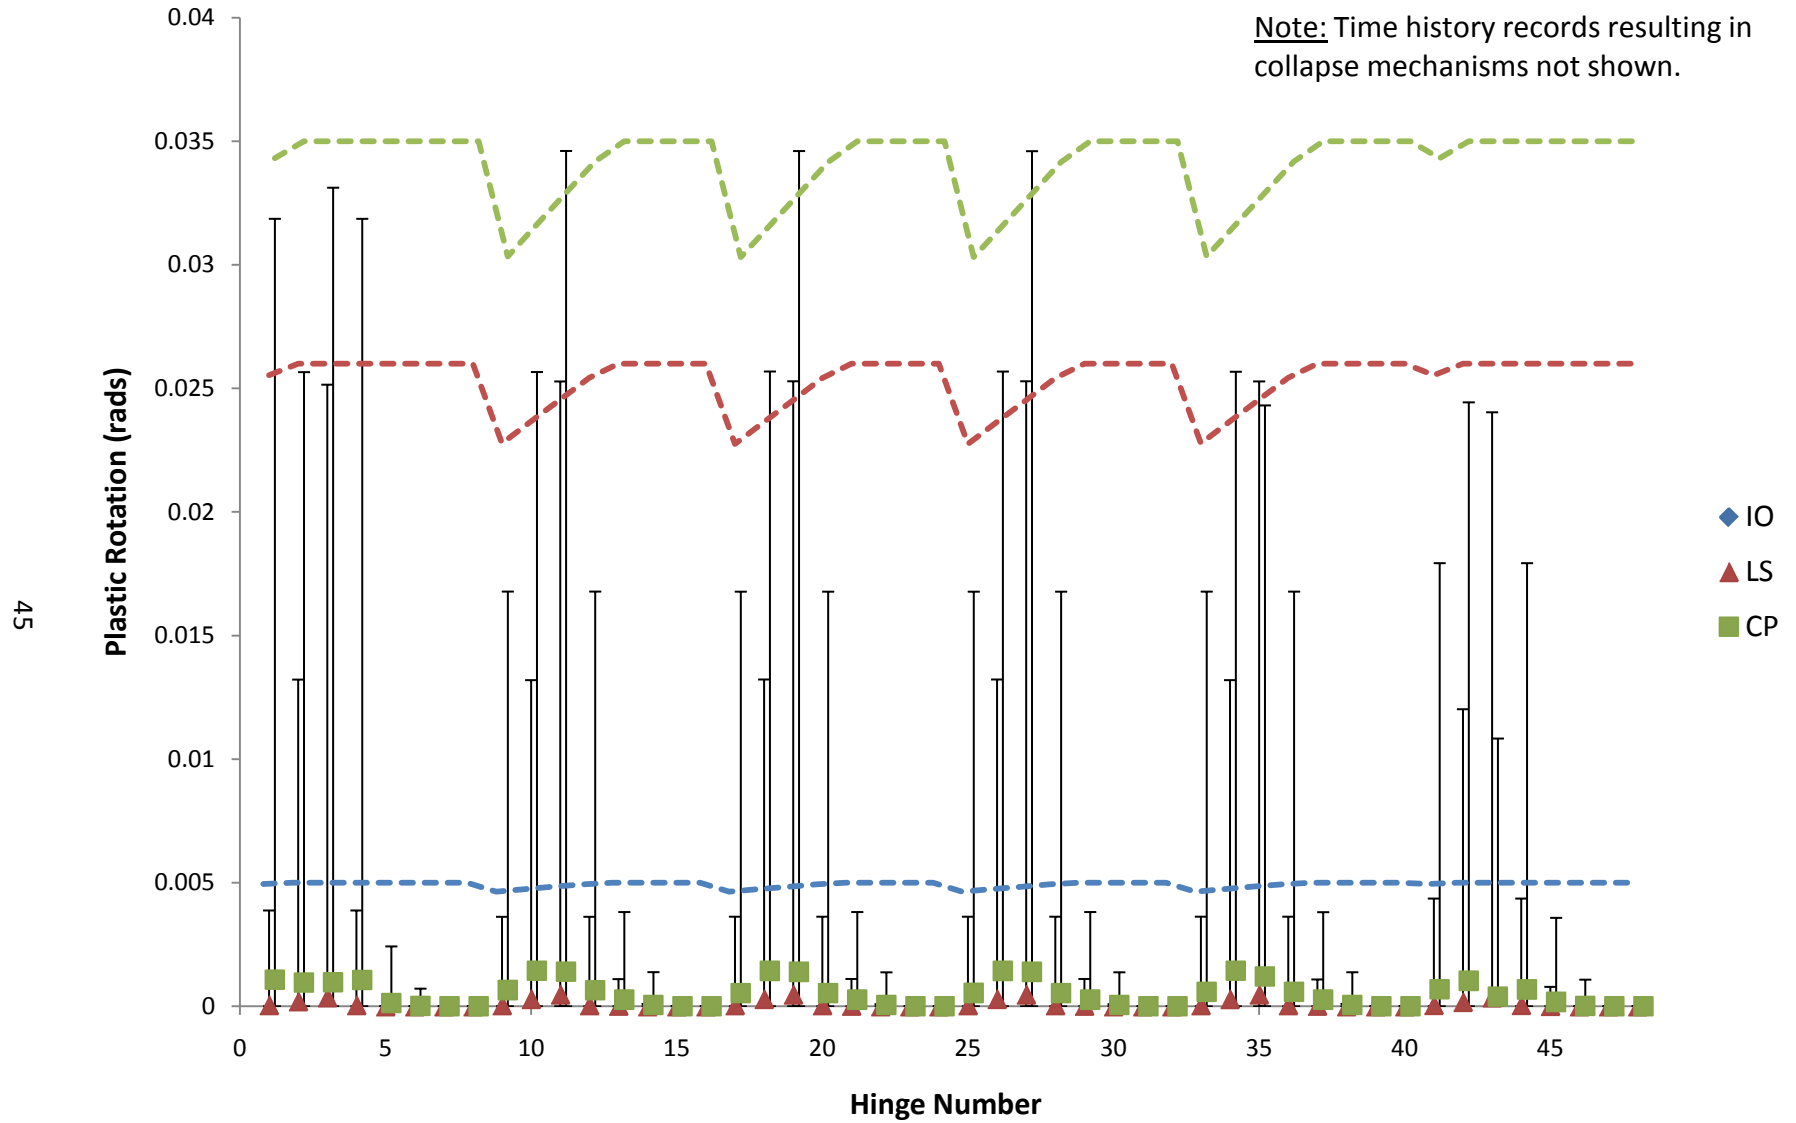

Figure 31. Top of Column Plastic Hinge Rotations

Plastic hinge rotations in the beams are generally within the prescribed ASCE/SEI 41-06 limits for all performance objectives. However, analysis indicates two IO level failures, occurring on the first and second levels. Similar to columns, however, these results are based on those time history records that do not cause a collapse mechanism. Figure 32 and Figure 33 indicate the various beam plastic hinge rotations at each performance objective for positive and negative flexure, respectively. The hinge numbers are arranged by level, all beams on one level in a row. Hinge numbers 1 through 40 represent hinges on the left side of the beam, while hinge numbers 41 through 80 represent hinges on the right side of the beam. Additionally, these figures indicate the maximum and minimum hinge rotations. As shown, the rotations at higher performance objectives, such as LS and CP, are relatively similar to those of the IO performance objective. This indicates that as the beams begin to yield, load is immediately transferred into the columns. This could be the cause of the collapse mechanisms found during analysis.

The overall behavior of the moment frame is indicative of the intended strong-column weak-beam design philosophy. As shown in the figures above, flexural rotations and yielding occur generally in the beams, and not in the columns. The locations of column yielding indicate a story shear type failure which results in collapse, and therefore these hinges are likely occurring just prior to collapse. Although this level of yielding is not desired at any performance objective, it does indicate behavior representative of design objectives. Figure 34 is a representative moment frame elevation showing the typical collapse mechanism for the CP performance objective. Again, yellow hinges indicate rotations beyond the CP objective limit. Support calculations for the moment frame using the NDP can be found in Appendix D.

Both exterior and interior shear walls experience plastic hinge rotations within prescribed ASCE/SEI 41-06 limits, at all performance objectives. Figure 35 and Figure 36 show plastic hinge rotations at each level of the interior and exterior shear walls, respectively. Hinge numbers are ordered by ascending floor level, and also indicate maximum and minimum rotation values. As shown in Figure 35, the largest plastic rotations occur on the second floor. This could be due to the relatively large change in reinforcing at this level. Conversely, as shown in Figure 36, rotations in the interior shear wall are at a maximum at the base and decrease relatively linearly with the height of the structure. This is likely the result of the generally typical reinforcing layout found in the interior shear walls. Rotations corresponding to the IO and LS objectives do, however, indicate clearly the relatively small change in reinforcing found at the first level of the interior shear walls. Support calculations for the exterior and interior shear walls using the NDP can be found in Appendix D.

Note: Time history records resulting in collapse mechanisms not shown.

4. CONCLUSIONS AND FUTURE RESEARCH NEEDS

4.1. Conclusions

A primary goal of ASCE/SEI 41-06 is to provide guidance on assessing the seismic performance of existing structures. Four different methods are prescribed, which include simpler, yet more conservative options, as well as complex options which more accurately represent the behavior of the structure. Assessment of the archetype structure exemplifies these varying approaches, as acceptance criteria are met at a much higher percentage for the more complex methods. However, the main objective of this investigation is to evaluate the procedures outlined in ASCE/SEI 41-06 for use in assessing new structures designed under ASCE/SEI 7-10 requirements.

Overall, the moment frames do not meet the acceptance criteria prescribed in ASCE/SEI 41-06. Throughout all linear and nonlinear procedures, beams and columns repeatedly do not meet assessment criteria. Additionally, use of the nonlinear dynamic procedure indicates a high collapse rate for the structure among various time history records at the collapse prevention performance objective. Although by code, the acceptance criteria can still be met, these collapse mechanisms would not be ignored in a design situation.

Shear walls, similar to moment frames, do not meet all of the acceptance criteria prescribed in ASCE/SEI 41-06. However, shear walls in general do meet the acceptance criteria at a much higher rate than the moment frames. In fact, use of nonlinear procedures results in both exterior and interior shear walls meeting all ASCE/SEI 41-06 requirements.

A likely cause for these discrepancies is the varying methods with which actions are imposed and resisted. ASCE/SEI 7-10 provides reduced design values, based on the ductility of the system, while ASCE/SEI 41-06 provides adjustment factors for component capacities. As these are different approaches, it is difficult to draw direct comparisons between the adjustment methods. However, the findings of this investigation do indicate that the two methods do not provide similar end results.

4.2. Further Research

Further research is needed to provide a more global view into the discrepancies found in this investigation. Varying parameters such as building layout, size, and lateral system could provide insight into the repeatability of the findings of this investigation.

Additionally, more detailed modeling should be investigated. As mentioned, an isotropic hardening hysteresis model is used in this investigation for the nonlinear dynamic procedure. To gain more accuracy, a Takeda model, which accounts for stiffness degradation, could be implemented. In addition, P-Delta effects were neglected for nonlinear procedures in order to resolve convergence issues. Further study should incorporate P-Delta effects to gain a more accurate view of how the structure behaves under seismic loading. Lastly, for nonlinear procedures, stick models are used for all shear walls to maintain simplicity. Flexural behavior in shear walls, however, is not fully captured using this method.

Use of a detailed fiber model of the shear walls should be used for the archetype structure in this investigation to compare the corresponding levels of accuracy.

D. Structural Systems

Select Structural System Types (ASCE 7-10 Table 12.2-1)

a. N-S Direction

A.1 "Special Reinforced Concrete Shear Walls"

R	5	Response Modification Factor (ASCE 7-10 Table 12.2-1)
Ω_0	2.5	System Overstrength Factor (ASCE 7-10 Table 12.2-1)
C_d	5	Deflection Amplification Factor (ASCE 7-10 Table 12.2-1)

a. E-W Direction

C.5 "Special Reinforced Concrete Moment Frames"

R	8	Response Modification Factor (ASCE 7-10 Table 12.2-1)
Ω_0	3	System Overstrength Factor (ASCE 7-10 Table 12.2-1)
C_d	5.5	Deflection Amplification Factor (ASCE 7-10 Table 12.2-1)

E. Structural Configuration

National Earthquake Hazards Reduction Program

Reference ASCE 7-10 Table 12.3-1,2 and apply required adjustments accordingly

*Note: Many Structural Irregularities (Horizontal, Vertical, and Torsional) require assumptions that must be verified after analysis is completed

F. Load Combinations

Basic Load Combinations (ASCE 7-10 Section 12.4.2.3 & 2.3.2)

- 1.4D
1.2D + 1.6L + 0.5Lr
1.2D + 1.6Lr + L
1.2D + 1.6Lr + 0.5W
1.2D + 1.0W + L + 0.5Lr
(1.2 + 0.2SDS)D + 0.5L1 +/- E
0.9D + 1.0W
(0.9 - 0.2SDS)D +/- E

1. Load factor for L permitted to be 0.5 for Live Loads less than or equal to 100 PSF

Section 2. Material Properties & Loading

A. Material Properties

Beams

Table with 2 columns: Property and Value/Description. Rows include f'c (5000), wc (150), fy (60), and SC_E (0.5).

*Note: Cracked scaling factor may be calculated or reasonably assumed per ACI 318-08 Section 10.10.4.1

Columns

Table with 2 columns: Property and Value/Description. Rows include f'c (5000), wc (150), fy (60), and SC_E (0.7).

*Note: Cracked scaling factor may be calculated or reasonably assumed per ACI 318-08 Section 10.10.4.1

National Earthquake Hazards Reduction Program

Walls

	Normal-Weight	Concrete Type
f'_c	5000	Concrete Compressive Strength, psi
Permitted per ACI 318 Section 21.2.4		
w_c	150	Unit Weight of Concrete, pcf
f_y	60	Reinforcing Steel Yield Strength, ksi
	ASTM A615*	Reinforcing Steel Designation
<i>*Note: Ensure compliance with ACI 318-08 Section 21.1.5.2.a,b</i>		
SC_E	0.8	Cracked moment of inertia scaling factor (applied to E in SAP2000)
<i>*Note: Cracked scaling factor may be calculated or reasonably assumed per ACI 318-08 Section 10.10.4.1</i>		

Slabs

	Normal-Weight	Concrete Type
f'_c	5000	Concrete Compressive Strength, psi
Permitted per ACI 318 Section 21.2.4		
w_c	150	Unit Weight of Concrete, pcf
f_y	60	Reinforcing Steel Yield Strength, ksi
	ASTM A615*	Reinforcing Steel Designation
<i>*Note: Ensure compliance with ACI 318-08 Section 21.1.5.2.a,b</i>		
SC_E	1.0	Cracked moment of inertia scaling factor (applied to E in SAP2000)
<i>*Note: Cracked scaling factor may be calculated or reasonably assumed per ACI 318-08 Section 10.10.4.1</i>		

B. Structural Design Loads

h	4.5	Typical slab thickness, in
L	102.3	N-S Building length parallel to secondary framing, ft
W	152.3	E-W Building length perpendicular to secondary framing, ft

	SW (PSF)	SDL _{seis} (PSF)	SDL _{nonseis} (PSF)	CL (PSF)	LL (PSF)	DL _{seis} (PSF)	DL _{nonseis} (PSF)
Level 08	56.25	20	20	15	20	76	76
Level 07	56.25	20	25	15	50	76	81
Level 06	56.25	20	25	15	50	76	81
Level 05	56.25	20	25	15	50	76	81
Level 04	56.25	20	25	15	50	76	81
Level 03	56.25	20	25	15	50	76	81
Level 02	56.25	20	25	15	50	76	81
Level 01	56.25	20	25	15	50	76	81
Level 00	56.25	20	25	15	100	76	81
Level A	56.25	20	25	15	40	76	81
Level B	56.25	20	25	15	40	76	81

Legend:

National Earthquake Hazards Reduction Program

- h Slab Thickness
- SW Self weight of slab
- SDL Superimposed dead load, including roofing, partitions, utilities, etc.
- LL Live Load (per ASCE 7-05 Table 4-1)

*Note: Applied cladding load uses user defined vertical tributary loads found in **Section 3**

Section 3. Section Properties, Stiffness Modifiers & Member Loads

*Note: Program is set up for typical floor framing configurations, table below may be duplicated and edited if levels have unique framing

A. Frame Beams

*Note: Beams are Modeled in ETABS as rectangular shapes below the slab as opposed to T-Beams

	W_{STEM}	H_{STEM}	b_{eff}	A_{STEM}	\bar{y}	I_{ETABS}	I_{ACTUAL}	SC_{I33}
	in	in	in	in ²	in	in ⁴	in ⁴	
FB1	24	27.5	27	660	17.88	41595.6	97131.7	2.335

Legend:

- W_{STEM} Stem width to be used in SAP2000
- H_{STEM} Height of stem below slab to be used in SAP2000
- b_{eff} Calculated effective flange extension, per ACI 318-08 Section 8.12
- SC_{I33} Major axis moment of inertia scaling factor used in SAP2000
- A_{STEM} Cross sectional area of stem

Unfactored Loads by Beam

Beam	Level	Horiz Trib (ft)	Vert Trib (ft)	LL (PLF)	CL (PLF)	DL _{TOT} (PLF)	
Level 08	FB1	Level 08	6.2	6.5	123	97.5	568
Level 07	FB1	Level 07	6.2	13	308	195	696
Level 06	FB1	Level 06	6.2	13	308	195	696
Level 05	FB1	Level 05	6.2	13	308	195	696
Level 04	FB1	Level 04	6.2	13	308	195	696
Level 03	FB1	Level 03	6.2	13	308	195	696
Level 02	FB1	Level 02	6.2	13	308	195	696
Level 01	FB1	Level 01	6.2	14	308	210	711

B. Frame Columns and Shear Walls

- 28** Typical column dimension, in
- 16** Typical shearwall width, in

C. Gravity Beam Unfactored Loads

Distributed Load Beams

Beam	Level	Grid Loc'n	Horiz Trib (ft)	LL (PLF)	DL (PLF)
------	-------	------------	--------------------	-------------	-------------

National Earthquake Hazards Reduction Program

GB1	08	1.5 - 5.5	10	200	763
GB1	07 - 01	1.5 - 5.5	10	500	813
GB1	00	1.5 - 5.5	10	1000	813
GB1	A	1.5 - 5.5	10	400	813

Cladding Load Beams

Beam	Level	Loc'n	Vert Trib	CL (DL) (PLF)
GB2	08	Perim	6.5	97.5
GB2	07 - 02	Perim	13	195
GB2	01	Perim	14	210

National Earthquake Hazards Reduction Program

Section 4. Seismic Modeling

A. Modeling Criteria

1. Foundation modeling is out of the scope of this program
2. Effective Seismic Weight (ASCE 7-10 Section 12.7.2)

*Note 1: In storage areas (not including public garages and open parking structures), a minimum of 25% of the floor live load should be included in the seismic weight of the structure

*Note 2: When partition loading is required, the greater of the partition weight or 10 psf should be included in the seismic weight of the structure

*Note 3: Total weight of operating machinery should be included in the seismic weight of the structure

*Note 4: Where the flat roof snow load exceeds 30 psf, a minimum of 20% of the uniform design snow load (regardless of roof slope) should be included in the seismic weight of the structure

B. Analysis Procedure Notes

*Note 1: Reference ASCE 7-10 Table 12.6-1 for permitted design procedures

*Note 2: Ensure after analysis that procedure is still permitted

*Note 3: Equivalent Lateral Method is required for base shear calculations, regardless of permitted analysis procedures, for scaling purposes

C. Equivalent Lateral Force Procedure, ELF (ASCE 7-10 Section 12.8)

1. Seismic Weight per Floor (From ETABS Model)

Level	Total Floor Weight (kips)	Total Floor Mass (k-s ² /ft)	Relative Mass Ratio (%)	Check ¹
Level 08	2277.2	70.72	94.34	PASS
Level 07	2413.7	74.96	100.00	PASS
Level 06	2413.7	74.96	100.00	PASS
Level 05	2413.7	74.96	100.00	PASS
Level 04	2413.7	74.96	100.00	PASS
Level 03	2413.7	74.96	100.00	PASS
Level 02	2413.7	74.96	100.00	PASS
Level 01	2460.1	76.40	101.92	PASS
Total	19220	597		

*Note: If check fails, a Mass Irregularity exists per ASCE 7-10 Table 12.3-2

2.a. Determine Period (N-S)

h_n **106** Height above base to highest level of structure, ft

C_w **0.0387** Coefficient for shear walls (if necessary)

*Note: Calculation of C_w based on ASCE 7-10 Equation 12.8-10

SW T_a **1.02** ($C_t \cdot h_n^x$) Approximate Period, sec (ASCE 7-10 Equation 12.8-7)

*Note: Values of C_t and x from ASCE 7-10 Table 12.8-2

$T_a \cdot C_u$ **1.43** Upper Limit Approx. Period, sec (ASCE 7-10 Section 12.8.2)

*Note: Value of C_u from ASCE 7-10 Table 12.8-1

T_{calc} **1.072** Calculated (ETABS, etc) Period, sec

National Earthquake Hazards Reduction Program

T	1.07	Period to be used for ELF, sec
<i>*Note: Use only the values of T corresponding to the structural system in use</i>		
T _{drift}	1.07	Period for use in calculating drifts, sec

Seismic Base Shear Calculation

T _L	8	Long Period Transition Period, sec (ASCE 7-10 Figure 22-15)
C _{s,max}	0.2000	(S _{DS} /(R/I)) Max Seismic Response Coefficient (ASCE 7-10 Equation 12.8-2)
C _{s,T}	0.1119	Adjusted Seismic Response Coefficient (ASCE 7-10 Equation 12.8-3,4)
C _{s,T}	0.1119	Adjusted Seismic Response Coefficient for Drift Calculations (No TaCu Limit per ASCE 7-10 Section 12.8.6.2)
C _{s,min}	0.0440	Min Seismic Response Coefficient (ASCE 7-10 Equation 12.8-5)
C _{s,S1}	0.0600	Min Seismic Response Coefficient for S1 ≥ .6g (ASCE 7-10 Equation 12.8-6)
C _s	0.1119	Seismic Response Coefficient to be used
C _{s,drift}	0.1119	Seismic Response Coefficient for Drift
V	2151	(C _s *W) Seismic Base Shear, kips (ASCE 7-10 Equation 12.8-1)
V _{drift}	2151	Seismic Base Shear for Drift Calculations, kip
S _{drift,NS}	1.00	V _{drift} / V

2.b. Determine Period (E-W)

h _n	106	Height above base to highest level of structure, ft
C _w	NA	Coefficient for shear walls (if necessary)

**Note: Calculation of C_w based on ASCE 7-10 Equation 12.8-10*

MRF	T _a	1.06	(C _t *h _n ^x) Approximate Period, sec (ASCE 7-10 Equation 12.8-7)
-----	----------------	-------------	--

**Note: Values of C_t and x from ASCE 7-10 Table 12.8-2*

	T _a *C _u	1.49	Upper Limit Approx. Period, sec (ASCE 7-10 Section 12.8.2)
--	--------------------------------	-------------	--

**Note: Value of C_u from ASCE 7-10 Table 12.8-1*

	T _{calc}	1.868	Calculated (ETABS, etc) Period, sec
--	-------------------	--------------	-------------------------------------

	T	1.49	Period to be used for ELF, sec
--	---	-------------	--------------------------------

**Note: Use only the values of T corresponding to the structural system in use*

	T _{drift}	1.87	Period for use in calculating drifts, sec
--	--------------------	-------------	---

Seismic Base Shear Calculation

T _L	8	Long Period Transition Period, sec (ASCE 7-10 Figure 22-15)
C _{s,max}	0.1250	(S _{DS} /(R/I)) Max Seismic Response Coefficient (ASCE 7-10 Equation 12.8-2)

National Earthquake Hazards Reduction Program

$C_{s,T}$	0.0504	Adjusted Seismic Response Coefficient (ASCE 7-10 Equation 12.8-3,4)
$C_{s,T}$	0.0401	Adjusted Seismic Response Coefficient for Drift Calculations (No $T_z C_u$ Limit per ASCE 7-10 Section 12.8.6.2)
$C_{s,min}$	0.0440	Min Seismic Response Coefficient (ASCE 7-10 Equation 12.8-5)
$C_{s,S1}$	0.0375	Min Seismic Response Coefficient for $S1 \geq .6g$ (ASCE 7-10 Equation 12.8-6)
C_s	0.0504	Seismic Response Coefficient to be used
$C_{s,drift}$	0.0401	Seismic Response Coefficient for Drift
V	968	$(C_s * W)$ Seismic Base Shear, kips (ASCE 7-10 Equation 12.8-1)
V_{drift}	772	Seismic Base Shear for Drift Calculations, kip
$S_{drift,EW}$	0.797	V_{drift} / V

3.a. Vertical Force Distribution (N-S)

k	1.29	Structure Period Exponent (ASCE 7-10 Section 12.8.3)					
Level	Height (ft)	$w_x * h_x^k$	C_{vx}^a	F_x^b (kips)	$F_{x,drift}$ (k)	V_x^c (kips)	M_x^d (k-ft)
Level 08	106	916097	0.235	505.3	505.3		
Level 07	93	820643.5	0.210	452.6	452.6	505.3	6,569
Level 06	80	676175.1	0.173	372.9	372.9	957.9	19,021
Level 05	67	538291.7	0.138	296.9	296.9	1330.9	36,323
Level 04	54	407890.7	0.105	225.0	225.0	1627.8	57,483
Level 03	41	286236.8	0.073	157.9	157.9	1852.7	81,569
Level 02	28	175279.3	0.045	96.7	96.7	2010.6	107,707
Level 01	15	80057.6	0.021	44.2	44.2	2107.3	135,102
Total			1.000	2151	2151	2151.4	167,373

a. Per ASCE 7-10 Equation 12.8-12

b. Per ASCE 7-10 Equation 12.8-11

c. Story shear

d. Overturning Moment

3.b. Vertical Force Distribution (E-W)

k	1.49	Structure Period Exponent (ASCE 7-10 Section 12.8.3)					
Level	Height (ft)	$w_x * h_x^k$	C_{vx}^a	F_x^b (kips)	$F_{x,drift}$ (k)	V_x^c (kips)	M_x^d (k-ft)
Level 08	106	2424735	0.253	245.2	195.5		
Level 07	93	2113573	0.221	213.7	170.4	245.2	3,187
Level 06	80	1687614	0.176	170.6	136.0	458.8	9,152
Level 05	67	1294663	0.135	130.9	104.4	629.5	17,335
Level 04	54	937842.5	0.098	94.8	75.6	760.4	27,220
Level 03	41	621364.6	0.065	62.8	50.1	855.2	38,338

National Earthquake Hazards Reduction Program

Level 02	28	351384.2	0.037	35.5	28.3	918.0	50,272
Level 01	15	140888.9	0.015	14.2	11.4	953.5	62,668
Total			1.000	968	772	967.8	77,185

- a. Per ASCE 7-10 Equation 12.8-12
- b. Per ASCE 7-10 Equation 12.8-11
- c. Story shear
- d. Overturning Moment

For Modelling Purposes, Ratio of Drift Base Shear to Strength Base Shear

0.797 E-W Ratio
1.000 N-S Ratio

4. Horizontal Force Distribution & Accidental Torsion

*Note: Accidental torsion calculated by multiplying the story force, F_x , by an eccentricity equal to 5% of the respective building width (ASCE 7-10 Section 12.8.4.2)

Level	Force, F_{NS} (kips)	Force, F_{EW} (kips)	NS Width (ft)	EW Width (ft)	NS Tors (k-ft)	EW Tors (k-ft)
Level 08	505.3	245.2	152.3333	102.3333	3849	1254
Level 07	452.6	213.7	152.3333	102.3333	3448	1093
Level 06	372.9	170.6	152.3333	102.3333	2841	873
Level 05	296.9	130.9	152.3333	102.3333	2261	670
Level 04	225.0	94.8	152.3333	102.3333	1714	485
Level 03	157.9	62.8	152.3333	102.3333	1202	321
Level 02	96.7	35.5	152.3333	102.3333	736	182
Level 01	44.2	14.2	152.3333	102.3333	336	73

*Note: Forces are derived from ELF Method 16387 4952

D. Modal Response Spectrum Analysis (ASCE 7-10 Section 12.9)

1. Elastic Response Spectrum Development (ASCE 7-10 Section 11.4.5)

Reference sheet "Response Spectrum Data" and copy spectrum to a .txt file, the user may now add this file in SAP as a Response Function to be used in analysis

2. Modal Mass Participation Factors

*Note: Prior to continuing through this section, the SAP model should be run to determine modes, etc.

Mode	Period (s)	% Effective Mass		
		N-S	E-W	Torsion
1	2.100	82.848	0.000	18.128
2	1.072	0.000	70.729	34.864
3	0.954	0.000	0.000	20.245
4	0.671	9.596	0.000	2.100
5	0.373	3.398	0.000	0.744
6	0.243	1.624	0.000	0.355
7	0.195	0.000	21.422	10.559

National Earthquake Hazards Reduction Program

8	0.189	0.000	0.000	5.810
9	0.173	0.827	0.000	0.181
10	0.146	0.000	0.000	0.000
11	0.146	0.000	0.000	0.000
12	0.139	0.000	0.000	0.000
Total		98.29	92.15	92.99
Check		OK	OK	OK

*Note: Per ASCE 7-10 Section 12.9.1, the number of modes investigated must represent at least 90% of the total mass

2. Scaling Requirements (ASCE 7-10 Section 12.9.4)

*Note: The elastic response spectrum requires scaling to achieve an approximate inelastic response spectrum as well as to ensure compliance with ASCE 7-10 Section 12.9.4. The final scaling factor should be applied as a load combination scale factor in SAP

*Note: The R factors for the two orthogonal building directions have been embedded into the calculated response spectrums in this workbook

*Note: A unit conversion of 1g = 32.2 ft/s² has been embedded into the response spectrums - ensure that the units in SAP comply, and scale the response spectrum accordingly if not

ξ **0.05** Damping Ratio

*Note: Typically, a damping ratio of 0.05 is used

Direction	V _{ELF} (kips)	0.85*V _{ELF} (kips)	V _{MRSA} (kips)	Force Scale Factor
N-S	2151	1829	2282.9	1.00
E-W	968	823	625	1.32

*Note: These scale factors should be applied in SAP as load combination scale factors (in addition to any other combination scaling)

E. Torsional Irregularities and Accidental Torsion Amplification

*Note: Input Displacements Based on Drift Load Combinations

Level	E-W Displacements		N-S Displacements	
	N Side (in)	S Side (in)	E Side (in)	W Side (in)
Level 08	3.607	3.754	3.770	2.851
Level 07	3.431	3.555	3.191	2.410
Level 06	3.137	3.239	2.612	1.971
Level 05	2.735	2.815	2.046	1.543
Level 04	2.248	2.307	1.507	1.137
Level 03	1.699	1.738	1.016	0.769
Level 02	1.112	1.134	0.594	0.453
Level 01	0.523	0.532	0.265	0.207
Base	0.005	0.005	0.035	0.033

*Note: The user should import or transpose the story drifts from the SAP model
Check E-W direction for Torsional Irregularity

National Earthquake Hazards Reduction Program

Level	Drift _N (in)	Drift _S (in)	Drift _{AVE} (in)	Max/Ave	Torsional Irregularity Exisits?
Level 08	0.141	0.158	0.150	1.059	NO

Amplification Needed?					NO

Torsional Irregularity Requirements

- 1** Increase in seismic forces calculated from ASCE 7-10 Section 12.8.1 for connections of diaphragms to vertical elements. Collectors and their connections shall be increased unless they are designed for the load combinations with overstrength factor of ASCE 7-10 Section 12.4.3.2 (ASCE 7-10 Section 12.3.3.4)
- NO** 3D Modeling requirement per ASCE 7-10 Section 12.7.3?
- NO** Story drift shall be calculated as the largest difference of the deflections along any of the edges of the structure at the top and bottom of the story under consideration (ASCE 7-10 Section 12.12.1)

Redundancy Factor

ρ_{EW}	1.0	Note Requirements per ASCE 7-10 Section 12.3.4
ρ_{NS}	1.3	Note Requirements per ASCE 7-10 Section 12.3.4

*Note: For ρ to be taken as 1.0, ensure all levels shown below that resist more than 35% of the total Base Shear comply with ASCE 7-10 Section 12.3.4.2.a or b

*Note: ρ applied to load combinations in SAP model where applicable

National Earthquake Hazards Reduction Program

- θ_{max} Max stability coefficient (ASCE 7-10 Equation 12.8-17)

5. Additional Notes

- a. Verify if a reentrant corner exists as defined in ASCE 7-10 Table 12.3-1(2)
- b. Verify if the diaphragm has a discontinuity irregularity as define in ASCE 7-10 Table 12.3-1(3)
- c. Verify if out-of-plane offsets exist as defined in ASCE 7-10 Table 12.3-1(4)
- d. Verify that the vertical resisting system components are parallel as defined in ASCE 7-10 Table 12.3-1(5)
- e. Verify if a vertical geometric irregularity exists as defined in ASCE 7-10 Table 12.3-2(3)
- f. Verify if an in-plane vertical irregularity exists as defined in ASCE 7-10 Table 12.3-2(4)
- g. Moment frame design should be checked for weak story requirements prescribed in ASCE 7-10 Table 12.3-2(5a, 5b)

Concrete Lateral Systems - Wind Forces

Section 6. Frame Design - Beams

*Note: Basis for design follows capacity-design method

*Note: Beams should be ordered similar to that of the SAP2000 Excel output for efficient data transfer

Typical Beam Properties

- 1.5** Minimum Clear Cover, in
- 5000** Concrete Compressive Strength, psi
- 60** Reinforcing Steel Yield Strength, ksi
- 1.0** Redundancy Factor (From Seismic Forces & Analysis)
- 4.5** Slab Thickness, in
- 0.002** Slab Reinforcement Ratio

Section 7. Frame Design - Columns

Typical Column Properties

- 5000** Concrete Compressive Strength, psi
- 60** Reinforcing Steel Yield Strength, ksi
- 28** Column width, in
- 1.5** Clear cover, in

*Note: PCA Column interaction diagrams should be attached for each unique column design, including all loading configurations on that unique column

Section 2b: LSP & NSP Moment Frame Beam Assessment (LS)

Typical Beam Properties

b_w	24	in, Beam Stem Width
h	32	in, Beam Height
b_e	27	in, Effective Beam Flange Extension
β_1	0.8	
c	1.5	in, Cover
	#4	Size of Transverse Reinforcing (Hinge Zone)
	3	Number of Legs in Transverse Reinforcing (Hinge Zone)
f'_c	5000	psi, Lower Bound Compressive Strength (ASCE 41-06 Table 6-3)
f_y	60	ksi, Lower Bound Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f_u	90	ksi, Lower Bound Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f'_c	7500	psi, Expected Compressive Strength (ASCE 41-06 Table 6-4)
f_y	75	ksi, Expected Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
f_u	113	ksi, Expected Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
κ	1	Knowledge Factor (ASCE 41-06 2.2.6.4)
C_1	1	
C_2	1	

Parameters Below Assume that $0 < \rho / \rho_{bal} < 5$, and Transverse Reinforcing Conforms. Check these values prior to using this portion of the table

BEAM ID	Existing Beam Reinforcing						M+		M-		$V_{DES,left}$	$V_{DES,middle}$	$V_{DES,right}$	$V/b_w d f_c^{1/2}$		$V/b_w d f_c^{1/2}$		$V_{\mu}/b_w d f_c^{1/2}$	$s_{h,L}$	$s_{h,R}$	Conform?	Conform?	M+		M-		M+		M-		Beam Flex

Section 3a: LSP & NSP Moment Frame Column Assessment (IO)

Typical Column Properties

w	28	in, Width of Column
c	1.5	in, Cover
β_1	0.8	
f'_c	5000	psi, Lower Bound Compressive Strength (ASCE 41-06 Table 6-3)
f_y	60	ksi, Lower Bound Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f_u	90	ksi, Lower Bound Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f'_c	7500	psi, Expected Compressive Strength (ASCE 41-06 Table 6-4)
f_y	75	ksi, Expected Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
f_u	112.5	ksi, Expected Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
k	1	Knowledge Factor (ASCE 41-06 2.2.6.4)
C_1	1	
C_2	1	
η	5.875	

Parameters Below Assume $P/A_g f'_c$ is less than 0.6, ρ is less than or equal to 0.5, ρ is greater than or equal to 0.006, and $V_u/A_g f_y$ is less than 0.6. Check these values prior to using this portion of the table

PCA Column Models should use expected behaviors

Section 3b: LSP & NSP Moment Frame Column Assessment (LS)

Typical Column Properties

w	28
c	1.5
β_1	0.8
f'_c	5000
f_y	60
f_u	90
f'_c	7500
f_y	75
f_u	112.5
κ	1
C_1	1
C_2	1
η	7.195

Parameters Below Assume $P/A_g f'_c$ is less than 0.6, s/d is less than or equal to 0.5, ρ is greater than or equal to 0.006, and $V_u/(V_u+N_u)$ is less than 0.6. Check these values prior to using this portion of the table

PCA Column Models should use expected behaviours

Section 3c: LSP & NSP Moment Frame Column Assessment (CP)

Typical Column Properties

w	28
c	1.5
β_1	0.8
f'_c	5000
f_y	60
f_u	90
f'_e	7500
f_y	75
f_u	112.5
κ	1
C_1	1
C_2	1
η	7.195

Parameters Below Assume $P/A_g f'_c$ is less than 0.6, s/d is less than or equal to 0.5, ρ is greater than or equal to 0.006, and $V_u/(V_u + N_u)$ is less than 0.6. Check these values prior to using this portion of the table

PCA Column Models should use expected behaviours

Section 4a: LSP Moment Frame Joint Assessment (IO)

Typical Joint Details

w	28	in, Column Dimension
A _j	784	in ²
C ₁	1	
C ₂	1	
f _c '	5000	psi, Lower Bound Compressive Strength of Concrete
f _y	60	ksi, Lower Bound Reinforcing Yield Strength
f _c '	7500	psi, Expected Compressive Strength of Concrete
f _y	75	ksi, Expected Reinforcing Yield Strength
κ	1	Knowledge Factor

National Earthquake Hazards Reduction Program

Section 4c: LSP Moment Frame Joint Assessment (CP)

Typical Joint Details

Table with 2 columns: Parameter and Value/Description. Parameters include w, A_j, C_1, C_2, f'_c, f_y, f'_c, f_y, and k.

Main data table with columns: Joint ID, Offset Rigidities, Joint Shear, and Joint Shear Acceptance. It lists 68 joints (6A01-6F08) with their respective properties and assessment results.

Section 5a: LSP & NSP Shear Wall Assessment (IO)

Typical Wall Properties

f'_c	5000	psi, Lower Bound Concrete Compressive Strength
f_y	60	ksi, Lower Bound Reinforcing Steel Yield Strength
f_u	90	ksi, Lower Bound Reinforcing Steel Ultimate Strength
f'_c	7500	psi, Expected Concrete Compressive Strength
f_y	75	ksi, Expected Reinforcing Steel Yield Strength
f_u	112.5	ksi, Expected Reinforcing Steel Ultimate Strength
t_w	16	in, Shear Wall Thickness
h_w	106	ft, Shear Wall Height
l_w	22.33	ft, Shear wall Length
Slender	Wall Slenderness (ASCE 41-06 Section C6.7.1)	
w	28	in, Boundary Element Width
A_g	4960	kips, Nominal Axial Capacity (No Eccentricity, Concrete Only)
κ	1.0	Knowledge Factor
C_1	1.0	
C_2	1.0

- Area of Longitudinal Steel in Boundary Elements
- If "NO", Shear Wall may not be taken as effective in resisting seismic forces per ASCE 41-06 Section 6.7.1.1
- Nominal Moment Capacity taken from PCA Column Analysis corresponding to minimum design Axial Load
- Nominal Moment Capacity at P=0 taken from PCA Column Analysis, including only boundary reinforcing. $\Phi = 1.0$, and expected strengths are used.
- Nominal Moment Capacity at P=0 is not required to exceed Moment Demand, as the compressive force is assumed to be 0 and therefore no interaction effects are taken into account.
- Maximum shear force calculated based on nominal flexural capacity of base of wall.
- Wall is considered controlled by flexure if the maximum shear force value is less than the nominal shear capacity. This indicates that the wall will fail in flexure prior to reaching the shear capacity.

- Area of Longitudinal Steel in Boundary Elements
- If "NO", Shear Wall may not be taken as effective in resisting seismic forces per ASCE 41-06 Section 6.7.1.1
- Nominal Moment Capacity taken from PCA Column Analysis corresponding to minimum design Axial Load
- Nominal Moment Capacity at P=0 taken from PCA Column Analysis, including only boundary reinforcing. $\Phi = 1.0$, and expected strengths are used.
- Nominal Moment Capacity at P=0 is not required to exceed Moment Demand, as the compressive force is assumed to be 0 and therefore no interaction effects are taken into account.
- Maximum shear force calculated based on nominal flexural capacity of base of wall.
- Wall is considered controlled by flexure if the maximum shear force value is less than the nominal shear capacity. This indicates that the wall will fail in flexure prior to reaching the shear capacity.

Section 5c: LSP Shear Wall Assessment (CP)

Typical Wall Properties

Table listing typical wall properties: f'c, fy, fu, fc', fy', fu', tw, hw, lw, Slender, w, Ag, K, C1, C2 with their respective units and descriptions.

Exterior Shear Wall

Table for Exterior Shear Wall assessment. Columns include Level, Elev, hseg, PDES,MAX, PDES,MIN, MDES,MAX, Horiz Reinf (Size, Spc), Vert Reinf (Size, Spc), Boundary Element (Size, Spc, Confined?, PCL, PCE), Effectiveness (Phi AXIAL, P > .35Po^2, sn > 18''^2, sv > 18''^2), Mn,P=0, VDES, VMAX, Vn,V, Control, J*PDES,MAX, J*PDES,MIN.

Interior Shear Wall

Table for Interior Shear Wall assessment. Columns include Level, Elev, hseg, PDES,MAX, PDES,MIN, MDES,MAX, Horiz Reinf (Size, Spc), Vert Reinf (Size, Spc), Boundary Element (Size, Spc, Confined?, PCL, PCE), Effectiveness (Phi AXIAL, P > .35Po^2, sn > 18''^2, sv > 18''^2), Mn,P=0, VDES, VMAX, Vn,V, Control, J*PDES,MAX, J*PDES,MIN.

- 1. Area of Longitudinal Steel in Boundary Elements
2. If "NO", Shear Wall may not be taken as effective in resisting seismic forces per ASCE 41-06 Section 6.7.1.1
3. Nominal Moment Capacity taken from PCA Column Analysis corresponding to minimum design Axial Load
4. Nominal Moment Capacity at P=0 taken from PCA Column Analysis, including only boundary reinforcing. Phi = 1.0, and expected strengths are used.
5. Nominal Moment Capacity at P=0 is not required to exceed Moment Demand, as the compressive force is assumed to be 0 and therefore no interaction effects are taken into account.
6. Maximum shear force calculated based on nominal flexural capacity of base of wall.
7. Wall is considered controlled by flexure if the maximum shear force value is less than the nominal shear capacity. This indicates that the wall will fail in flexure prior to reaching the shear capacity.

Section 7a: LDP (Response Spectrum) Moment Frame Column Assessment (IO)

Typical Column Properties

w	28	in, Width of Column
c	1.5	in, Cover
β_1	0.8	
f'_c	5000	psi, Lower Bound Compressive Strength (ASCE 41-06 Table 6-3)
f_y	60	ksi, Lower Bound Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f_u	90	ksi, Lower Bound Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f'_c	7500	psi, Expected Compressive Strength (ASCE 41-06 Table 6-4)
f_y	75	ksi, Expected Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
f_u	112.5	ksi, Expected Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
k	1	Knowledge Factor (ASCE 41-06 2.2.6.4)
C_1	1	
C_2	1	
η	7.195	

Parameters Below Assume $P/A_g f'_c$ is less than 0.6, s/d is less than or equal to 0.5, ρ is greater than or equal to 0.006, and $V_u/P_u A_g$ is less than 0.6. Check these values prior to using this portion of the table

PCA Column Models should use expected behaviours

Section 7b: LDP (Response Spectrum) Moment Frame Column Assessment (LS)

Typical Column Properties

Table with 2 columns: Property Name and Value. Properties include width (w), cover (c), effective depth (d), concrete strength (f'c), yield strength (fy), ultimate strength (fu), expected concrete strength (fc'), expected yield strength (fy'), and ultimate strength (fu').

Parameters Below Assume P/A_g f'c is less than 0.6, s/d is less than or equal to 0.5, p is greater than or equal to 0.006, and V_u/(V_u/d) is less than 0.6. Check these values prior to using this portion of the table

PCA Column Models should use expected behaviours

Main data table with columns for COL ID, I_n, Longit Reinf, Yield Zone, Non-Yield Zone, Top Bottom, P_DESIGN, Q_c/A_g f'c, x E_L, J^P_DESIGN, and Flexure-Axial (M_DESIGN).

Section 8a: LDP (Response Spectrum) Moment Frame Joint Assessment (IO)

Typical Joint Details

Table with 2 columns: Parameter and Value/Description. Parameters include w, A_j, C_1, C_2, f'_c, f_y, f'_c, f_y, k.

Linear Dynamic Procedure table with columns: Joint ID, Offset Rigidities, Joint Shear, J, Q_UF (V_j), Condition, Int/Ext, Q_CL (V_n), Joint Shear Acceptance.

National Earthquake Hazards Reduction Program

Section 8b: LDP (Response Spectrum) Moment Frame Joint Assessment (LS)

Typical Joint Details

Table with 2 columns: Parameter and Value/Description. Parameters include w, A_j, C_1, C_2, f'_c, f_y, f'_c, f_y, K.

Main data table titled 'Linear Dynamic Procedure'. Columns include Joint ID, Offset Rigidities, Joint Shear, J, Q_UF, Condition, Int/Ext, Q_CL, and Joint Shear Acceptance.

National Earthquake Hazards Reduction Program

Section 8c: LDP (Response Spectrum) Moment Frame Joint Assessment (CP)

Typical Joint Details

Table with 2 columns: Parameter and Value/Description. Parameters include w, Aj, C1, C2, fc', fy, fc', fy, K.

Main data table with columns: Joint ID, ΣMnc/ΣMnb, Offset Rigidities (Col, Beam), Joint Shear (Vg,L, Vg,R), J, QUF (Vj), Condition, Int/Ext, QCL (Vn), Joint Shear Acceptance.

**Section 9a: LDP (Response Spectrum) Shear Wall Assessment (IO)**

Typical Wall Properties

f'_c	5000	psi, Lower Bound Concrete Compressive Strength
f_y	60	ksi, Lower Bound Reinforcing Steel Yield Strength
f_u	90	ksi, Lower Bound Reinforcing Steel Ultimate Strength
f'_c	7500	psi, Expected Concrete Compressive Strength
f_y	75	ksi, Expected Reinforcing Steel Yield Strength
f_u	112.5	ksi, Expected Reinforcing Steel Ultimate Strength
t_w	16	in, Shear Wall Thickness
h_w	106	ft, Shear Wall Height
l_w	22.33	ft, Shear wall Length
Slender		Wall Slenderness (ASCE 41-06 Section C6.7.1)
w	28	in, Boundary Element Width
A_b	4960	kips, Nominal Axial Capacity (No Eccentricity, Concrete Only)
k	1.0	Knowledge Factor
C_1	1.0	
C_2	1.0

1. Area of Longitudinal Steel in Boundary Elements

2. If "NO", Shear Wall may not be taken as effective in resisting seismic forces per ASCE 41-06 Section 6.7.1.1

3. Nominal Moment Capacity taken from PCA Column Analysis corresponding to minimum design Axial Load

4. Nominal Moment Capacity at P=0 taken from PCA Column Analysis, including only boundary reinforcing. $\Phi = 1.0$, and expected strengths are used.

5. Nominal Moment Capacity at P=0 is not required to exceed Moment Demand, as the compressive force is assumed to be 0 and therefore no interaction effects are taken into account.

6. Maximum shear force calculated based on nominal flexural capacity of base of wall.

7. Wall is considered controlled by flexure if the maximum shear force value is less than the nominal shear capacity. This indicates that the wall will fail in flexure prior to reaching the shear capacity.

1. Area of Longitudinal Steel in Boundary Elements

2. If "NO", Shear Wall may not be taken as effective in resisting seismic forces per ASCE 41-06 Section 6.7.1.1

3. Nominal Moment Capacity taken from PCA Column Analysis corresponding to minimum design Axial Load

4. Nominal Moment Capacity at P=0 taken from PCA Column Analysis, including only boundary reinforcing. $\Phi = 1.0$, and expected strengths are used.

5. Nominal Moment Capacity at P=0 is not required to exceed Moment Demand, as the compressive force is assumed to be 0 and therefore no interaction effects are taken into account.

6. Maximum shear force calculated based on nominal flexural capacity of base of wall.

7. Wall is considered controlled by flexure if the maximum shear force value is less than the nominal shear capacity. This indicates that the wall will fail in flexure prior to reaching the shear capacity.

Section 10b. LDP (Time History) Moment Frame Beam Assessment (LS)

Typical Beam Properties

b_w	24	in, Beam Stem Width
h	32	in, Beam Height
b_e	27	in, Effective Beam Flange Extension
β_1	0.8	
c	1.5	in, Cover
	#4	Size of Transverse Reinforcing (Hinge Zone)
	3	Number of Legs in Transverse Reinforcing (Hinge Zone)
f_c'	5000	psi, Lower Bound Compressive Strength (ASCE 41-06 Table 6-3)
f_y	60	ksi, Lower Bound Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f_u	90	ksi, Lower Bound Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f_c^e	7500	psi, Expected Compressive Strength (ASCE 41-06 Table 6-4)
f_y^e	75	ksi, Expected Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
f_u^e	113	ksi, Expected Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
κ	1	Knowledge Factor (ASCE 41-06 2.2.6.4)
C_1	1	
C_2	1	

Parameters Below Assume that $\phi_p/\phi_{bal} < 5$, and Transverse Reinforcing Conforms. Check these values prior to using this portion of the table

BEAM ID	Existing Beam Reinforcing					M+			M-			$V_{DES,left}$	$V_{DES,middle}$	$V_{DES,right}$	$S_{h,L}$	$S_{h,R}$	Conform?	Conform?	Beam Flexure Acceptance

Section 10c. LDP (Time History) Moment Frame Beam Assessment (CP)

Typical Beam Properties

b_w	24	in, Beam Stem Width
h	32	in, Beam Height
b_e	27	in, Effective Beam Flange Extension
β_1	0.8	
c	1.5	in, Cover
	#4	Size of Transverse Reinforcing (Hinge Zone)
	3	Number of Legs in Transverse Reinforcing (Hinge Zone)
f_c'	5000	psi, Lower Bound Compressive Strength (ASCE 41-06 Table 6-3)
f_y	60	ksi, Lower Bound Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f_u	90	ksi, Lower Bound Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f_c^e	7500	psi, Expected Compressive Strength (ASCE 41-06 Table 6-4)
f_y^e	75	ksi, Expected Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
f_u^e	113	ksi, Expected Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
k	1	Knowledge Factor (ASCE 41-06 2.2.6.4)
C_1	1	
C_2	1	

Parameters Below Assume that $\phi_p/\phi_{bal} < 5$, and Transverse Reinforcing Conforms. Check these values prior to using this portion of the table

BEAM ID	Existing Beam Reinforcing						M+			M-			$V_{DES,left}$	$V_{DES,middle}$	$V_{DES,right}$	$S_{h,L}$	$S_{h,R}$	Conform?	Conform?	Beam Flexure Acceptance

Section 11a. LDP (Time History) Moment Frame Column Assessment (IO)

Typical Column Properties

w	28	in, Width of Column
c	1.5	in, Cover
β_1	0.8	
f'_c	5000	psi, Lower Bound Compressive Strength (ASCE 41-06 Table 6-3)
f_y	60	ksi, Lower Bound Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f_u	90	ksi, Lower Bound Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f'_c	7500	psi, Expected Compressive Strength (ASCE 41-06 Table 6-4)
f_y	75	ksi, Expected Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
f_u	112.5	ksi, Expected Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
κ	1	Knowledge Factor (ASCE 41-06 2.2.6.4)
C_1	1	
C_2	1	
η	7.195	

Parameters Below Assume $P/A_g f'_c$ is less than 0.6, s/d is less than or equal to 0.5, ρ is greater than or equal to 0.006, and $V_u/(V_u/k)$ is less than 0.6. Check these values prior to using this portion of the table

PCA Column Models should use expected behaviours

Section 11b. LDP (Time History) Moment Frame Column Assessment (LS)

Typical Column Properties

w	28	in, Width of Column
c	1.5	in, Cover
β_1	0.8	
f'_c	5000	psi, Lower Bound Compressive Strength (ASCE 41-06 Table 6-3)
f_y	60	ksi, Lower Bound Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f_u	90	ksi, Lower Bound Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f'_c	7500	psi, Expected Compressive Strength (ASCE 41-06 Table 6-4)
f_y	75	ksi, Expected Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
f_u	112.5	ksi, Expected Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
κ	1	Knowledge Factor (ASCE 41-06 2.2.6.4)
C_1	1	
C_2	1	
η	7.195	

Parameters Below Assume $P/A_g f'_c$ is less than 0.6, s/d is less than or equal to 0.5, ρ is greater than or equal to 0.006, and $V_u/(V_u/k)$ is less than 0.6. Check these values prior to using this portion of the table

PCA Column Models should use expected behaviours

Section 11c. LDP (Time History) Moment Frame Column Assessment (CP)

Typical Column Properties

w	28	in, Width of Column
c	1.5	in, Cover
β_1	0.8	
f'_c	5000	psi, Lower Bound Compressive Strength (ASCE 41-06 Table 6-3)
f_y	60	ksi, Lower Bound Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f_u	90	ksi, Lower Bound Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-2)
f'_c	7500	psi, Expected Compressive Strength (ASCE 41-06 Table 6-4)
f_y	75	ksi, Expected Yield Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
f_u	112.5	ksi, Expected Ultimate Strength of Reinforcing Steel (ASCE 41-06 Table 6-4)
κ	1	Knowledge Factor (ASCE 41-06 2.2.6.4)
C_1	1	
C_2	1	
η	7.195	

Parameters Below Assume $P/A_g f'_c$ is less than 0.6, s/d is less than or equal to 0.5, ρ is greater than or equal to 0.006, and $V_u/(V_u/s)$ is less than 0.6. Check these values prior to using this portion of the table

PCA Column Models should use expected behaviours

National Earthquake Hazards Reduction Program

Section 12a. LDP (Time History) Moment Frame Joint Assessment (IO)

Typical Joint Details

Table with 2 columns: Parameter and Value/Description. Parameters include w, A_j, C_1, C_2, f'_c, f_y, f'_c, f_y, and k.

Main data table with columns: Joint ID, Offset Rigidities, Joint Shear, J, Q_UF (V_j), Condition, Int/Ext, Q_CL (V_n), and Joint Shear Acceptance. Rows list various joint IDs from 6A01 to 6F08.

National Earthquake Hazards Reduction Program

Section 12b. LDP (Time History) Moment Frame Joint Assessment (LS)

Typical Joint Details

Table with 2 columns: Parameter and Value/Description. Parameters include w, A_j, C_1, C_2, f'_c, f_y, f'_c, f_y, and k.

Main data table with columns: Joint ID, Offset Rigidities, Joint Shear, and Joint Shear Acceptance. It lists 80 joints (6A01-6F08) with their respective properties and assessment results.

National Earthquake Hazards Reduction Program

Section 12c. LDP (Time History) Moment Frame Joint Assessment (CP)

Typical Joint Details

Table with 2 columns: Parameter and Value/Description. Parameters include w, A_j, C_1, C_2, f'_c, f_y, f'_c, f_y, and k.

Main data table with columns: Joint ID, Offset Rigidities, Joint Shear, and Joint Shear Acceptance. It lists 68 joints (6A01-6F08) with their respective properties and assessment results.

**Section 13a. LDP (Time History) Shear Wall Assessment (IO)**

Typical Wall Properties

f'_c	5000	psi, Lower Bound Concrete Compressive Strength
f_y	60	ksi, Lower Bound Reinforcing Steel Yield Strength
f_u	90	ksi, Lower Bound Reinforcing Steel Ultimate Strength
f'_c	7500	psi, Expected Concrete Compressive Strength
f_y	75	ksi, Expected Reinforcing Steel Yield Strength
f_u	112.5	ksi, Expected Reinforcing Steel Ultimate Strength
t_w	16	in, Shear Wall Thickness
h_w	106	ft, Shear Wall Height
l_w	22.33	ft, Shear wall Length
Slender		Wall Slenderness (ASCE 41-06 Section C6.7.1)
w	28	in, Boundary Element Width
A_b	4960	kips, Nominal Axial Capacity (No Eccentricity, Concrete Only)
k	1.0	Knowledge Factor
C_1	1.0	
C_2	1.0

1. Area of Longitudinal Steel in Boundary Elements

2. If "NO", Shear Wall may not be taken as effective in resisting seismic forces per ASCE 41-06 Section 6.7.1.1

3. Nominal Moment Capacity taken from PCA Column Analysis corresponding to minimum design Axial Load

4. Nominal Moment Capacity at P=0 taken from PCA Column Analysis, including only boundary reinforcing. $\Phi = 1.0$, and expected strengths are used.

5. Nominal Moment Capacity at P=0 is not required to exceed Moment Demand, as the compressive force is assumed to be 0 and therefore no interaction effects are taken into account.

6. Maximum shear force calculated based on nominal flexural capacity of base of wall.

7. Wall is considered controlled by flexure if the maximum shear force value is less than the nominal shear capacity. This indicates that the wall will fail in flexure prior to reaching the shear capacity.

1. Area of Longitudinal Steel in Boundary Elements

2. If "NO", Shear Wall may not be taken as effective in resisting seismic forces per ASCE 41-06 Section 6.7.1.1

3. Nominal Moment Capacity taken from PCA Column Analysis corresponding to minimum design Axial Load

4. Nominal Moment Capacity at P=0 taken from PCA Column Analysis, including only boundary reinforcing. $\Phi = 1.0$, and expected strengths are used.

5. Nominal Moment Capacity at P=0 is not required to exceed Moment Demand, as the compressive force is assumed to be 0 and therefore no interaction effects are taken into account.

6. Maximum shear force calculated based on nominal flexural capacity of base of wall.

7. Wall is considered controlled by flexure if the maximum shear force value is less than the nominal shear capacity. This indicates that the wall will fail in flexure prior to reaching the shear capacity.
